- cw break-in system
- rf bypassing
In a time when transceivers are a dime a dozen,

ours costs an arm and a leg.

The signal/one CX7A will set you back $2,195 — but set you way ahead in amateur radio operation.

That's because the CX7A has just about every feature you can think of. Including the most sensitive receiver made, the most "talk-powered" 300 watts of power you ever heard, and much more. Like an extra receiver, an RF clipper, a built-in power supply and an electronic keyer.

Suddenly, $2,195 sounds more like a bargain than a bundle. Because you're getting, in effect, a room full of gear in one compact desk-top unit. A unit that features the industry's highest quality control standards, the finest components obtainable, the most features, the best performance... we could go on.

Better yet, you go on over to your signal/one dealer and see the rig for yourself. Or write us for a detailed brochure. Once you see the CX7A, you'll be willing to give up an arm and a leg for it. Or at least $2,195.

**6 & 2 METER MOBILE**

Heavy duty, precision fit, four section telescopic antenna tunable separately for combined six and two meter operation. Extends to 44". collapses to 22".

**Model HF-2:** Antenna supplied with 3/4"-24 base to fit any standard antenna mount. $9.50

**Model HF-62:** Supplied with automotive eight ball base for fender or cowl mounting. Includes 60" RG-58-U and connectors. $11.95

**Tops in rooftops**

**140-500 MHz—UHF/VHF Antenna**

Low profile, roof top with factory attached cable—installs from outside without disturbing car header. 17-7 PH stainless radiating element—field trimmed for frequencies between 140 and 500 MHz. Complete with 17" RG-58-U coaxial cable.

**Model UHT-1**

$7.75

**Trunk Lip Mount**

**140-500 MHz UHF/VHF**

Easy to install on side or rear of trunk lip. No holes to drill or coax to trim. 17-7 PH stainless steel radiating element. Chart included for 140-500 MHz coverage. Complete with 17" RG-58-U and PL-259.

**Model THF**

$12.95

**NEW!**

**2 METER POWER GAIN**

**143-149 MHz**

3.4 db gain—% wavelength

Power rating: 200 watts FM

Get the experience of solid communications, extended range and full quieting with the Hustler BBL models. Optimized gain performance with lowest SWR and the superior mechanical construction will give you the extra advantage. Both models supplied operational, ready for easy installation.

**Model BBL-144:** Mounts on any flat surface in 3/4" hole—easy installation on roof, (without pulling cars' header), deck or fender—complete with adjustable, taper ground stainless steel radiator, stainless steel spring. Overall height approximately 47", 17" RG-58-U coax with PL-259 connector. $27.70

**Model BBLT-144:** Same as BBL-144 with Hustler trunk lip mount for no holes to drill installation on side or rear of trunk lip. Heavy duty mount assures "stay-put" operation, positive RF ground for lowest SWR and completely hidden cable. $34.70

Exclusive Hustler "break cable" assembly for simplest installation of all!

World leader in Antenna Mounts—send for Catalog today!

The best antenna of its type on the market. Four wide spaced elements (the longest 36'6'') on a 26' boom along with Hy-Gain's exclusive Beta Match produce a high performance DX beam for phone or CW across the entire 20 meter band.

- 10 db forward gain
- 28 db F/B ratio
- Less than 1.05:1 SWR at resonance
- Feeds with 52 ohm coax
- Maximum power input 1 kw AM; 4 kw PEP
- Wind load 99.8 lbs. at 80 MPH
- Surface area 3.9 sq. ft.

The 204BA Monobander is ruggedly built to insure mechanical as well as electrical reliability, yet light enough to mount on a lightweight tower. (Recommended rotator: Hy-Gain's new Roto-Brake 400.) Construction features include taper swaged slotted tubing with full circumference clamps; tilttable cast aluminum boom-to-mast clamp; heavy gauge machine formed element-to-boom brackets; boom 2" OD; mast diameters from 1½" to 2½"; wind survival up to 100 MPH. Shipping weight 51 pounds.

See the best distributor under the sun... the one who handles the Hy-Gain 204BA Monobander.

- Model 204BA (4-element, 20 meters) $149.95
- Model 203BA (3-element, 20 meters) $139.95
- Model 153BA (3-element, 15 meters) $69.95
- Model 103BA (3-element, 10 meters) $54.95

FERRITE BALUN MODEL BN-86

Improves transfer of energy to the antenna; eliminates stray RF; improves pattern and F/B ratio. $14.95

A whole new field of electronics may eventually evolve from current research into semiconductor vacuum tubes. Sound like an April-fool joke? Well, interest in this area has been high since RCA successfully operated a silicon-cold-cathode tube several months ago. In this device the cathode is a silicon p-n junction which emits electrons directly into a vacuum when the diode is forward biased.

The latest solid-state cold-cathode vacuum tubes use gallium phosphide as the cathode material. The surface of the gallium phosphide is coated with a layer of cesium or cesium oxide which allows the electrons to escape into the vacuum. Although the maximum current densities are presently quite small, and must be increased significantly before the solid-state vacuum tubes are practical for commercial use, technology moves very rapidly, and we should see practical devices of this type on the market within the next five years.

Because of another recent advance in electronic technology noisy cooling fans and blowers may shortly be giving way to a completely new cooling concept which uses, of all things, an electrostatic discharge. The heat is removed by the corona discharge from the negative ends of high-voltage probes — there is no arcing. According to the inventor, Oscar Blomgren, a red-hot heat sink at 1675° Fahrenheit can be cooled to a dark 975° (a drop of 700 degrees) in one or two seconds with a 30-kV, 200-μA electrostatic discharge.

Blomgren accidentally discovered the cooling phenomenon of high-voltage discharges while attempting to keep an acetylene flame from touching the inside of a pipe by using an electric field; he was trying to solve a burner-nozzle deterioration problem.

There is still much to be learned about the way the discharge cooling system works, but apparently the corona discharge or electric wind creates vortex columns in the air next to the heated surface. Normally, a thin layer of air clings to the surface; this acts as an insulating barrier which inhibits the rate at which adjacent cooling air can carry away the heat. With the high-voltage electric field, the cooling rate is increased by the swirling action of the vortex columns which pull in cooler air from outside the normal boundary area.

To compare electrostatic cooling with forced-air cooling, engineers set up an aluminum block and heated it to 250° F. With constant heat input, the temperature decreased at the rate of 8° per minute when the high-voltage was turned on. When a blower was used, the temperature dropped 11° per minute, but 14 watts were required for the blower as opposed to 3 watts for the electrostatic system.

In another experiment engineers heated two high-power transistor heat sinks to 500° F with blow torches. With the burners adjusted to stabilize the temperatures of both heat sinks to 500°, a 28-kV electric field applied to one heat sink reduced its temperature by 185 degrees; the other heat sink remained at 500°.

Amateurs who would like to experiment with electrostatic cooling need an adjustable high-voltage power supply, 20 to 30 kV. The unit to be cooled is connected to ground with the negative lead of the supply; the positive lead is connected to a pointed probe. No noticeable cooling takes place until the discharge current is greater than about 10 μA; this is controlled by the supply voltage and the spacing between the probe and the unit being cooled.

Swan introduces a complete 2-element beam antenna package direct from our factory, at tremendous savings! Now, ONLY SWAN HAS IT ALL! Pack includes:

- **Swan TB-2 Beam Antenna** ........................................... $79.00 list.
- **40' Rohn-Spaulding EP-5 Tower** ................................ $89.00 list.
- **AR-22 Rotor** .......................................................... $59.95 list.
- **100' Rotor Cable** .................................................... $6.00 list.
- **100' RG-8/U Cable** .................................................. $16.00 list.

Total list cost $250.00

**SWAN'S GIANT KILLER PRICE FOR ALL**

While the price is a bargain, the two-element beam antenna package is the finest you could own at any price! The Swan TB-2 antenna traps are wound on pre-grooved Lexon coil forms, and precision tuned at the factory for consistent superior performance. These are the same traps that we use on all Swan triband antennas. And only Swan offers precision cast aluminum boom to mast and other element fittings. The driven elements are supported by lightweight precision machined aluminum casting, so that they won't work loose under heaviest storm conditions. All fittings are of the same heavy-duty construction as our multi-element beam antennas. The Rohn-Spaulding EP-5 40' tower is made of the same highest quality materials that have made Rohn-Spaulding towers the largest in the nation. The tower can be ground mounted with base plate and adjustable house bracket as furnished.

Now you have the convenience of having a complete antenna and tower assembly from one source, at a 30% savings, and you can charge it all to your Swan credit account.

**MONEY BACK GUARANTEE**

Since this low price is possible only by direct factory purchase, you can order your Swan Giant Killer Pack by mailing in the coupon at right. If you are not completely satisfied, return the antenna to Swan and we will refund the full purchase price to you by return mail.

**Gentlemen:**

Please send me your Giant Killer Pack.

The Best Vertical There IS!
80 through 10 meters

**hy-gain** 18AVT/WB

New, from the inventors of wideband verticals.
Pack some punch! All the omnidirectional performance of Hy-Gain's famous 14AVQ/WB...plus 80 meter capability! Unrivaled performance, rugged extra heavy duty construction, and the price you want...all in one powerful package!

- Automatic switching on all five bands through the use of three beefed-up Hy-Q traps...featuring extra large diameter coils for exceptional L/C ratio and extremely high Q.
- Recessed coax connector furnished.
- Top loading coil and four element static hat.
- Constructed of extra heavy wall high tensile aluminum.
- Hot performance all the way across the band with just one setting (10 through 40).
- Hy-Q traps effectively isolate antenna sections for full 1/4 wave resonance on all bands.
- No dissimilar metals to cause noise.
- SWR 2:1 or less at band edges.
- Maximum legal power with low frequency drift.
- Exceedingly low radiation angle makes DX and long haul contacts a cinch...whether roof or ground mounted.
- Very low RF absorption from insulating materials.

The 18AVT/WB is constructed of extra heavy duty, taper swaged, seamless aircraft aluminum with full circumference, corrosion resistant compression clamps at all tubing joints. This antenna is so rigid, so rugged...that its full 25' height may be mounted using only a 12" double grip mast bracket...no guy wires, no extra support...the 18AVT/WB just stands up and dishes it out!

Order No. 386  
$59.95

HY-GAIN FACTORY AUTHORIZED CLEARANCE

**FM-210 2 METER TRANSCEIVER**
Regular Price $229.50

**PA-210 2 METER 35 WATT MOBILE AMPLIFIER**
Regular Price $149.95

A $378.45 VALUE  BOTH ONLY $299.95

**FM 2 METER TRANSCEIVER:**
Top performance as fixed or mobile unit, direct or through repeater. The first American made 2 meter transceiver specifically designed for amateur use. True FM and discriminator detection. Plug-in devices for easy service. Rugged chassis construction and advanced electronic circuitry. Separate transmit and receive frequency controls for 9 channel combination capability.

**SPECIFICATIONS:**
- Frequency Range: 143-149 MHz
- Antenna Impedance: 50 Ohms
- Nominal Power Reqmts: 12-14 VDC (or optional power booster)
- Transmitter: Power Input: 5 watts (10 W. with pow. booster)
- Freq. Control: 3 Chan.* crystal controlled
- Microphone: High Impedance req'd.

*Furnished with 146.94 crystal for transmit and receive

**PA-210 2 METER 35 WATT MOBILE AMPLIFIER.**
Rugged solid state amplifier with 35 watts output to boost your range. A must for areas where there is no repeater available. Specifically designed for use with the FM-210. Unique circuit protects the output transistor from voltage spikes and surges. All changes over relay functions are internal and controlled by FM-210 circuitry through connecting cable.

**SPECIFICATIONS:**
- Input Voltage: 12v DC, negative ground only
- Power Input: 60 watts
- Power Output: 35 watts
- Frequency Range: 143-149 MHz

**ORDER DIRECT!**
Send check, money order, or use your BankAmericard or Master Charge (please include account number).

More Details? CHECK-OFF Page 94
Upon acquiring a new teletype machine, I was faced with the problem of coming up with a terminal unit, or TU — the black box between the transceiver and the teleprinter. I didn’t want to be bothered with unwinding toroids and selecting odd-ball capacitor values to adapt some of the TUs that were holdovers from the past decade. I wanted a TU that was totally new in its detection method. This TU was to be “state of the art” and thus different in design from current units.

I’d had some experience with the phase-locked loop (PLL or PL²) in the telemetry field and knew it to be an excellent fm demodulator. However, the discrete circuitry was rather complex. While deliberating, I received a notice from Signetics announcing their new PL² in an IC. This announcement, together with subsequent attendance at their technical seminar, pointed the way for my new TU design — a phase-locked loop detector.* With the help of Art Fury, WA6JLJ, and his staff at Signetics, my project has progressed from a dream to reality — all in one year.

*The circuit is now patent pending, and the PC boards (available from WCI, Box 17, Schaumburg, Ill. 60172) are copyrighted.
the phase-locked loop

The PL\textsuperscript{2} as an afsk detector is an entirely new approach to RTTY demodulation. No toroids or LC-tuned circuits are used. The entire TU occupies two 4-inch-square PC boards. The PL\textsuperscript{2} detector will work with 6-dB or lower signal-plus-noise-to-noise ratios. No scope tuning provisions are needed; a pair of light-emitting diodes provide all tuning indications. Features of the PL\textsuperscript{2} afsk demodulator are:

1. Automatic shift selection, allowing automatic copy of any shift from 150 to 1000 Hz without manual switching.
2. Afc, which provides automatic lock-in; signals drifting as much as ±500 Hz can be followed.
3. Automatic threshold corrector.
4. Antispacer control.
5. Autostart, with solid-state printer motor control.
6. A 170-volt loop supply, coupled with extremely sharp selector-magnet pulses, and a constant-current selector magnet driver.
7. Operation with ssb audio passbands (low tones) or regular RTTY tones at the flip of a switch.
8. Squelch circuit, which prevents printing on noise.

characteristics

The phase-locked loop has an extremely linear voltage-controlled oscillator (vco) whose center frequency is set to the midrange of frequencies being detected. A simplified functional diagram of the Signetics NE565K IC phase-locked loop is shown in fig. 1. An RC network sets the resting or center frequency, \( F_{CO} \), of the vco. When a signal is applied to the phase-comparator input, its frequency and thus its phase is compared with \( F_{CO} \). If the vco frequency is different from \( F_{CO} \), an error voltage is generated at the phase-comparator output. This error voltage is then amplified, filtered, and fed to the frequency-control input of the vco. The error voltage causes the vco frequency to shift to that of the applied

![fig. 1. Oversimplified diagram of Signetics NE565K phase-locked loop. Loop 6-dB roll-off point is where \( X_C \) of \( C_{FO} \) equals 3.6 k ohms.](image-url)
input signal. This action nulls the error-voltage output from the phase comparator, and the loop is phase locked.

If the input frequency varies within the vco frequency range, the error voltage applied to the vco is the duplicate of the frequency modulation applied to the PL², and is thus the demodulated output. The vco output may also be used as it has an approximately 40-dB S+n/n ratio over the input signal, and the vco tracking-response rate may be controlled by an external low-pass filter capacitor. Thus the PL² may be used as an fm detector/discriminator and as a tracking filter.*

development

The recommended circuit for the Signetics NE565K phase-locked loop required a dual-voltage power supply. This was contrary to my basic premise for an afsk detector; namely, to keep it simple. More reading and experimentation showed that the PL² would work with a single-polarity 12-Vdc supply. The recommended S5710 voltage comparator wouldn't operate with a single-polarity supply, but I found that the S5741T would. So I used a NE565K-S5741T combination for my first detector (fig. 2A).

The S5741T is internally compensated and develops more than 100-dB voltage gain. The NE565K provides approximately 100-mV change at pin 7 for 200-Hz frequency change at the input. This

*The phase-locked loop isn't new. In the 1950s a modified version of the PL² described here was used to provide phase-coherent reference signals in a tracking station at the Kennedy Space Center. This early circuit, using tubes, occupied half of a 6-foot relay rack. Two technicians were assigned full time during range operations merely to check for balanced sets of tubes! editor.
detector followed RTTY signals from 170-Hz narrow shift to 850-Hz wide shift, and even followed commercial 425-Hz-shift stations — all without switching or adjustments!

A three-section RC filter eliminated the VCO carrier frequency on which the demodulated information appeared at pin 7. The one drawback to this circuit was that receiver tuning had to be just right to keep the PL² output swinging symmetrically on either side of the reference voltage at pin 6. If the receiver or received signal drifted, then the output from the comparator became asymmetrical, and the printer either ran open or refused to print (figs. 2B and 2C).

Tracking problems

The problem was clear but baffling. The reference voltage must shift in proportion to the amount of tuning error so that the comparator output remained symmetrical. If the demodulated output voltage swing could be averaged, then this voltage could be used as a reference voltage, which would move with the demodulated output-voltage swing. But this had to be done without disturbing the PL² output.

My approach was to integrate the total swing, thus obtaining an average, or mid-point, of the demodulated-voltage swing that could be used as a reference (fig. 3). This reference voltage would then shift with the voltage swing of the PL² output if the applied frequencies were (a) offset from the VCO center frequency, or (b) different because of frequency drift in the receiving equipment.

Since the shortest RTTY pulse at 60 wpm is 22 ms, I chose integrator time-constant values that provided 15 times the shortest pulse, or 0.33 second, so that the integrator followed the average swing of about 3 RTTY characters at 60 wpm. Resistor R₁ (fig. 3) unbalances the input to the N5741T tracking comparator so its output remains in mark with no signal applied to the PL²; thus the machine does not run open. The output voltage from pin 7 of the phase-locked loop was about 10.6 volts with no input.

[Diagram]

fig. 4. Dashed line represents reference point of input to tracking comparator as a result of the low-pass filter. Note that reference point is always at the midpoint of the demodulated voltage swing regardless of signal amplitude, which is proportional to frequency shift.

January 1972
detector performance

The circuit of fig. 3 worked as well as I had expected. Even slight mistuning of afsk frequencies had no effect on printer operation so long as these frequencies fell within the lock-in range of the PL$^2$. This range was about $\pm 50$ percent of the vco center frequency. The low-pass filter was increased to 4 sections to obtain another 6 dB of vco carrier suppression and slightly improved performance. I now had a workable detector that had a form of afc and automatic shift selection — the reference point would always be at the midpoint of the afsk input demodulated swing regardless of the demodulated swing amplitude, which is proportional to the input-frequency shift. (See fig. 4.)

The differential input of the PL$^2$ was terminated to present a 600-ohm load at the input. This termination was ac coupled to ground through a capacitor, as the inputs require positive bias voltage for normal operation. The PL$^2$ has very high input sensitivity and will operate on signals in the order of 100 mV p-p or less. A simple diode limiter was placed in the input to avoid overdriving the PL$^2$.

No predetection filtering was used because I wanted to retain the maximum bandwidth of the PL$^2$. Thus the only predetection filtering or input-bandwidth restrictions are those of the receiver rf-af passband and a single-section RC filter in the vco control-voltage circuit; thus the PL$^2$ operates as a second-order loop. Its response is limited to 450 Hz by the 0.1-µF capacitor between pin 7 and $+V_{cc}$ (fig. 2).

squelch circuit

Much on-the-air testing followed. The PL$^2$ and tracking comparator worked extremely well. However, one problem continued to annoy me. When tuning from one RTTY station to another, or when an RTTY station went off the air, random noise caused the printer to print random characters. This was because of the tracking comparator high gain and the wide bandwidth of the PL$^2$ and its RC filter. A method was needed to put the printer in a nonprint or mark-hold mode in the absence of a valid RTTY signal, or in the presence of random noise. A simple noise squelch would do the job but would require another stage that could be squelched. I selected a type TAA-560 Schmitt trigger by Amperex for this circuit (fig. 5). The TAA-560 requires a trigger voltage of only 1.5 volts. The tracking comparator output is of the order of 10 V p-p (in the space condition), so input to the Schmitt trigger is controlled by a voltage divider.

The PL$^2$ noise voltage is of insufficient amplitude for use as a squelch voltage; however, the tracking-comparator output is high enough for this application. (Also, I didn't want the 22-ms TTY pulses to activate the squelch circuit.) I sampled the tracking comparator output with a differentiating circuit. This network had little response to the comparatively long RTTY pulses, which have approximately a 25-Hz rate. The differentiating network responded to pulses with a frequency of 200 Hz or higher. Its design frequency is approximately 200 Hz at the 6 dB point, and it works like a simple RC high-pass filter.

The pulses from the differentiating network are coupled to a voltage doubler circuit. The rectifier output voltage is applied to a filter capacitor with a bleeder resistor in the form of a pot across it. The combination of the 10-µF filter shunted by the 100-k pot provided a discharge time constant of about 1 sec. The charge time is limited only by the circuit impedance and is about 10 ms. The output arm of the squelch pot was also fed to the Schmitt trigger input through a 100-k isolation resistor.

When the detector is fed raw audio noise from the receiver, the squelch pot is adjusted until the machine stops chattering on noise. The negative voltage from the squelch rectifier keeps the Schmitt trigger biased off. The Schmitt output will remain in the mark condition with random noise at the PL$^2$ input, or when
the RTTY signal fades into the noise to the point where the PL\(^2\) unlocks. In the absence of an input to the PL\(^2\), integrator resistor, R11, at the tracking comparator input unbalances the static positive volt-
age at the differential input; thus the tracking comparator output remains in mark.

**Post Detection Filtering**

The tracking comparator output is fed through a voltage divider to a two-section RC low-pass ladder filter. The filter output is fed to the Schmitt trigger, which functions as a pulse regenerator. The Schmitt trigger output pulse rise time is 10\(\mu\)s.

If it's desired to pass a square-wave pulse through a network without distorting the pulse waveshape, the network should pass a frequency at least ten times (preferably 20 times) higher than the pulse frequency. However, when maximum signal-to-noise ratio is desired, mini-
mum bandwidth must be used. A minimum-bandwidth filter, unfortunately, also distorts an applied square wave; so a square-wave signal from a narrow-band filter must be reshaped. Hence the TAA-560 IC in fig. 5.

When the pulse is regenerated great care must be taken not to induce pulse-width distortion. The only place that a non-square-wave pulse may be sampled (for regenerating purposes) is at the 50% maximum voltage point, where the pulse rise-time delay is exactly equal to the fall-time delay. In this way the pulse is delayed because of the narrow filter bandpass, but its width doesn't change during regeneration or shaping. The regenerator output produces the exact duplicate (possibly better) of the original pulse before entering the narrow-bandpass filter; or, in this case, a low-pass filter.

design evaluation

The signal is now pure, has a square waveshape, and no noise exists except for a small amount that's within the same frequency spectrum as the desired signal. If this noise isn't of sufficient amplitude to trigger the pulse regenerator, the pulse won't appear in the regenerator output. The RC low-pass filter 6-dB point, between the tracking comparator and the Schmitt trigger, is at 25 Hz. If 100 wpm operation is desired, the capacitors in the filter (C15; C18 in fig. 5) should be .022 μF.

The PL$^2$ afsk detector has now met all design objectives:

1. Simple circuitry.
2. Copies all normal fsk shifts.
3. Mark-hold feature on random noise.
4. Works with low-frequency tones for ssb receivers and transceivers at the flip of a switch.
5. Afc circuit allows drifting or mistuned signals to be received with high-accuracy printout.
6. Tracking comparator provides anti-space function as the PL$^2$ shifts to the space frequency. If no shift, tracking comparator reverts to mark-hold mode.

TU performance data

Tests and measurements verified that the PL$^2$ provided 98% correct copy with
less than 6 dB s+n/n at the input, where noise was Gaussian from 0-5 kHz. Figs. 6 and 7 respectively show response curves and the test instrumentation used to obtain the data.

Approximately 8 dB improvement was obtained over a Foster-Seeley discriminator. The only disadvantage of the PL2 afsk detector was its wide bandwidth. The operational bandwidth is equal to the width, in Hz, of the fsk being received. The noise bandwidth is equal to the capture range, or about 1200 Hz. If an interfering signal 5-6 dB stronger than the desired signal falls in the PL2 operational pass-band, it will capture the vco much like the fm capture effect. Other than this one minor detriment, everything is in the PL2 afsk detector's favor.

The vco center frequency can be set by an external resistor, so two pots and a switch were used. One pot sets the vco to 1500 Hz for use with ssb receivers and transceivers having limited audio pass-bands, thus the TU will operate on tones from 800-2200 Hz. The other pot sets the vco for 2550 Hz for normal RTTY tones, and the TU will operate on tones in the 1800-3200 Hz range. This made an afsk detector that is compatible with any communications receiver used for RTTY.

selector-magnet driver, autostart, and fsk

During the initial development of the PL2 afsk detector, I used a Teletype Corporation Model 32 machine. This machine has a built-in solid-state SMD, loop-current sensing amplifier, and power supply. The SMD in the Model 32 was driven with a 12-volt, 60-mA loop supply directly from the Schmitt trigger output, with a 150-ohm resistor in the 12-volt supply to set loop current to 60 mA. (This resistor was also connected to the Schmitt trigger output via the TT loop.)

Most RTTY enthusiasts have TT machines that require an external dc-loop supply. These supplies have outputs ranging from 24 to 200 Vdc. The higher the voltage, the better will be the rise and fall times on the selector-magnet keying pulses. Thus the machine will operate on keying pulses with a wide range of distortion.

I wanted my selector-magnet driver transistor to key the loop at or very near ground potential. Also I wanted the stage to operate as a constant-current regulator so the keying-pulse waveform would be flat. I used a simple pnp transistor pre-driver (fig. 8) to develop forward bias across a pot for the SMD. This pot allows small changes to be made in loop current if TT machines are used that have different selector-magnet coil resistances.

Note that loop-voltage drop, when the loop is keyed or in mark, is obtained across an external resistor (R_ex in fig. 8). This protects the driver transistor from thermal overload.

autostart

The keyboard is connected in series with the SMD transistor emitter to ground. Isolation diodes connected to the junction of the SMD transistor emitter and keyboard allow keying of other circuits (fsk, afsk, etc.) with the keyboard. Such circuits are not disturbed when the loop is keyed in the receive mode by the SMD transistor, because the keyboard contacts are normally closed. This feature is important if you're using a transceiver with only a single vfo and you have it hooked up with the fsk circuit. When operating in this manner, it's necessary to offset receiver tuning with the incremental-tuning control to obtain the
afsk tones for the TU. I wanted a simple autostart circuit that would respond only to a fsk signal, and which wouldn’t respond to a steady mark tone or a slow transition from mark to space and back at

trolled triac, called a “Magtrac,” whose reed-relay coil is IC compatible. This device will drive TT machines with motor-current requirements of 3 amps running and 12 amps starting, which

a slow rate, as is the case when someone is checking his fsk shift.

**motor control**

In my original circuit, the Schmitt trigger output was also fed through an isolation diode to a voltage divider and RC network. The output from the network would control a relay driver. However, I didn’t want to use a large contactor relay in my final design. A trip to Magneraft Corporation proved fruitful in this regard. They had a reed-relay-con-

cludes any Teletype Corporation printer motor in amateur service. The schematic is shown in fig. 8.

In my final design (fig. 8) I used the TAA-560 to drive the Magtrac because the TAA-560’s high input impedance doesn’t load the RC circuit. In fact, I had to add a discharge resistor to obtain proper autostart turn-off time. The Magtrac offers great isolation between input and output while allowing a low-level logic signal to control a fairly high ac load.

---

**fig. 8. Schematic of selector-magnet driver and autostart circuits. Patent pending by WCl, 1971.**
Signal-One provisions

Out of necessity I added a circuit to key a negative voltage to operate the transmit fsk keying provision of the pull-out transistors, ICs, and diodes—use new devices that meet manufacturer’s specs. You’ll save yourself a lot of headaches.

The TU occupies two 4 x 4-inch plug-

Signal-One CX-7 transceiver. (Several minor modifications are needed on the CX-7 for RTTY operation; but properly modified, the CX-7 works beautifully on RTTY.)

This circuit is also shown in fig. 8. A Litronix Iso-Lit 1, an electro-optical isolator, is used, which is a LED-control-led pnp photo transistor. A single transistor drives the Iso-Lit and also conditions the fsk signal so that mark is high in frequency on transmit and space is lower in frequency. The amount of shift is set by the front-panel fsk control on the CX-7.

construction notes

When building the PL2 TU I didn’t skimp on parts. Only the highest-grade commercial-quality components were used. All resistors are 5%, and capacitors are 10% tolerance. I recommend MIL-spec low-leakage electrolytic capacitors. Stick with the exact component values and don’t substitute! Also don’t use in PC boards. Standard 22-pin PC connectors are used, which fit a Cinch-Jones type 50-22A-20 socket. The entire main frame (fig. 9) of the RD-100 was built on a Bud AC-407 chassis. The unit is enclosed in an LMB CO-2 cabinet and front panel. The cabinet and panel, finished in two-tone gray, is a dead ringer for a piece of the S-line series.

The 12-volt dc power supply should be extremely well regulated with better than 0.1% regulation. I used a commercial unit with excellent performance, a Lambda Electronics Corp. Model LZS-11; quite a buy for only $38.00.

The loop supply is similar to that used by W6FFC in his ST-6—nice and healthy. Voltage is about 170 Vdc, and the supply provides better than 250 mA, of which only 60 mA are used. But the voltage stays put! Even if the voltage varies slightly, the constant-current characteristic of the SMD holds the loop at 60 mA on mark.

Resistor $R_{ext}$ (fig. 8) is mounted directly on the chassis, which provides a heat sink. Be sure to use a small amount of Wakefield thermal compound to ensure good thermal contact to the chassis.

All input and machine-connection jacks are mounted on the chassis rear deck. The selector-magnet jack and plug are three-circuit types; however, only two circuits are used, as both sides of the selector-magnet coil are above ground. A grounding-type ac receptacle is also mounted on the chassis rear. This is the ac output line from the autostart, and the machine motor is plugged in here. Both power-supply primaries are fused. The 12-volt load of the unit is 50-60 mA.

**initial setup and checkout**

For the setup you’ll need a vom and a frequency counter or oscilloscope and a calibrated af oscillator. These last two items can be used to read frequency in place of a counter. The oscilloscope can also be very helpful should you have to go “pulse hunting.” The oscillograms of fig. 10 will aid in alignment and checkout of both units.

1. Plug in the machine motor, keyboard, and selector magnets. Plug in the ac power to the RCT. Don’t connect your receiver to the RCT at this time. Function switch should be in autostart; mode switch in ssb.

2. Connect a counter to TP-2 of the detector board and make sure that the mode switch is in ssb. Adjust R5 for a counter reading of 1500 Hz. This is the vco center frequency adjustment for ssb mode.

3. Place the mode switch in NORM and adjust R6 for a counter reading of 2500 Hz. This is the vco center frequency adjustment for the NORM mode.

4. Now connect your receiver 500-600 ohm audio to the RCT input. Set the volume at a comfortable level and tune to a clear frequency. The noise may trigger the autostart ON, but don’t worry. Now adjust noise-squelch pot R16 to the point where the machine stops printing on impulse noise; ten seconds later the autostart will turn the motor OFF.

5. Place a 20-k/V vom or vtvm from TP-3 on the SMD board to ground, and adjust the loop-current-adjust pot for 3.75 Vdc. You now have 60 mA in the loop.

6. If you’re using an ssb receiver or transceiver, enable the ssb mode and place the receiver/transceiver in Isb. Place the RCT in the ssb mode and tune to a RTTY station so that you can hear both tones. The RCT will do the rest.

If you’re using a receiver with an af passband up to 3 kHz, then you can use the NORM mode on the RCT.

**sources**

1. The PL2 (NE565K) and the tracking comparator (N5741T) are available from Signetics Corp., 811 East Arques Ave., Sunnyvale, Ca. 94086. The NE565K is approximately $11.00; the N5741T is approximately $1.50.

2. The Schmitt trigger, type TAA-560, is available from Amperex Electronics Corp., I. C. Division, Providence Pike, Slatesville, R. I. 02876. The TAA-560 is approximately $3.00.

4. The 12 Vdc regulated power supply, model LZS-11, is available from Lambda Electronics Corp., 515 Broad Hollow Road, Melville, L. I., New York, 11746 for $38.00.

5. The Iso-Lit 1 is available from Litronix Corp., 19000 Homestead Road, Cupertino, Ca. 95014, for about $4.00.

introduction to microwaves

A discussion of the differences between low frequencies and the microwave domain in terms of ac-circuit theory.

The amateur bands above 1 GHz offer interesting challenges to the builder-experimenter and operator alike. Known as the microwave region, this portion of the radio spectrum is relatively unpopulated with amateur signals when compared to the lower-frequency bands. Many amateurs don't understand the theoretical and physical concepts of microwave work and tend to ignore this interesting facet of ham radio. Many of the devices used at the microwave frequencies were developed in laboratories by physicists; consequently the behavior of such devices is usually described in complex mathematical terms. However, by using a logical down-to-earth approach, microwave fundamentals are easily understood.

50 MHz and up

Construction technique and operating know-how in the region above 50 MHz is much different than in the "dc bands." Getting equipment to work at, say, 1296 MHz is a real test of one's ability in circuit design techniques and testing. If you like to build equipment, here's a fertile field for your ingenuity and patience. Like to work DX without the hassles and pile-ups of 20 meters? Try over-the-horizon work with narrowband equipment on 3300 and 5650 MHz.¹ Try
some of the experiments with ROCLOC (relative or crystal local oscillator control), a technique developed by the San Bernardino Microwave Society.²

Many other activities will be found in the amateur bands above 50 MHz. Com-
munications by tropo scatter, meteor scatter, and moonbounce are examples. Recent work by amateurs has established the practicability of communications over long paths on frequencies to at least 10,000 MHz. Interested in building equipment? Here's a remark by an East-coast microwave enthusiast, K2JNG: "You don't buy gear for this band (1296 MHz), you build it."³

These are but a few of the happenings in the bands above 50 MHz. Now let's look at some of the differences in techniques and technical disciplines required for microwave work as compared to those associated with the lower frequencies.

background

Electricity that alternates with time, whether from power mains, radio-broad-
cast stations, or radar is described in terms of an alternating wave. It makes no difference whether the circuit involves vacuum tubes, transistors, transmission lines or antennas; the resulting pheno-
menon may be attributed to a series of waves. Scientists recognized the similarity between these various waves before the turn of the century and segregated them by frequency as shown in fig. 1. For reasons we will see shortly, this band of frequencies is called the electromagnetic spectrum. All waves within the electromagnetic spectrum travel at the speed of light — 300 million meters/sec or about 186,000 miles/sec. If the operating fre-
quency is 10 billion cycles/sec (10,000 MHz) the alternating wave will go through one complete cycle in one ten-
billionth of a second. Since the wave moves at 300 million meters/sec, it will

---

fig. 1. The electromagnetic spectrum.

fig. 2. The wavelength equation.

The increasing use of microwaves in recent years parallels the expansion to the hf and vhf portions of the spectrum of a few years ago. In all cases the spectrum has become crowded with radio services, and it has been necessary to expand in the only possible direction, upward. Measured in cycles, the additional fre-
frequencies made available by the advent of microwave technology are several hundred times greater than all those previously available. These additional frequencies are not a panacea, however, because many of the new services require wide bandwidths. Radar, for example, requires a bandwidth of 5 to 10 MHz.

**bandwidth considerations**

The microwave frequencies are especially important for two reasons, both based on the peculiarities associated with ultra-short wavelengths. The first is the bandwidth consideration; a radio signal consisting of only one frequency isn’t practical for the transmission of intelligence, because a single-frequency signal is infinitely narrow. Information may be carried by a signal only if it occupies a restricted band of frequencies. In general, the wider the band, the more information can be conveyed per unit time. The intelligence may consist of telegraphic dots and dashes, audio or video modulation, radar pulses, etc. In each case a certain bandwidth must be assigned to provide distortion-free transmission and reception.

When the operating frequency is very high to start with, a given bandwidth constitutes a smaller percentage of the carrier frequency, and it’s possible to provide more channels of intelligence. For example, if we modulated a 10-MHz radio signal with video 2 MHz wide, the bandwidth would constitute 20% of the carrier frequency. If, on the other hand, we modulated a 100-MHz signal with the same video information, the resultant bandwidth would be only 2%. In general, it’s difficult to obtain bandwidths greater than about 5% of the carrier frequency.

Bandwidth becomes increasingly important when the modulating signal is characterized by an inherently wide bandwidth. This is the case with the very short pulses associated with radar and pulse-code communications systems, or where the multiplexing of a large number of video channels by a single transmitter results in economic television relay service.

**antennas**

The second major consideration has to do with antennas. Both the beamwidth and the gain of an antenna depend upon the ratio of the wavelength to the size of the antenna. In many applications, it’s desirable to concentrate the radiated energy into very narrow cones a few degrees wide, with gains of several thousand. This can be done only when the antenna is extremely large in terms of operating wavelength and is impossible when the wavelength is measured in miles. However, extremely high-gain antennas are practical with wavelengths less than an inch.

**atmospheric noise**

Very low atmospheric noise exists in the microwave region. A “low-noise window” extends from 200-1500 MHz where atmospheric noise is almost nonexistent. Additionally, the very short wavelengths associated with microwave frequencies are suited to many unique construction techniques. Hollow pipes may be used for transmission lines, cavity resonators with extremely high Qs may be used in place of LC circuits, and parabolic reflectors may replace massive directive antenna arrays.

**electrical concepts**

The misunderstanding and confusion surrounding microwaves is due in part to the apparently different electrical concepts that govern their operation. Actually the concepts are not so very different from those encountered at lower frequencies; it’s just that the laws used at the lower frequencies are not sufficiently
general to encompass microwave circuits. This difference is comparable to the difference between dc and ac circuit theory. After studying dc circuits, it's necessary to have an understanding of frequency, phase, and reactance before ac circuits may be properly analyzed.

In dc and low-frequency communications, it's customary to consider the transmission of energy through the flow of current or electrons. In the microwave region this concept may be misleading, because it doesn't explain the transmission of energy through a hollow waveguide where conventional current does not exist. If, instead, we consider that energy is contained in an electromagnetic field, the transmission phenomenon at any radio frequency may be easily explained.

Many tend to forget the basic elements of static electricity and charges once the concepts of voltage, current, and Ohm's law are understood. This isn't too unusual, because these latter units are easily measured in everyday electronics circuitry. However, at microwave frequencies, the familiar quantities of voltage and current are difficult, if not impossible, to measure, and we must resort to the fundamental concepts of electric and magnetic fields to understand microwave theory.

electrical fields

Before progressing into a general discussion of fields, let's consider the concepts of electric fields and electric voltage. Actually, they are very closely related quantities, with field strength expressing the force that would be felt by an electron placed at some point in space and voltage expressing the product of this field strength and the distance over which it moves the electron. Contrary to what you might think, this is not a new idea at all. If you'll recall your first studies in electricity, you'll no doubt remember the experiments with cat fur and a rubber rod. When you rubbed the fur with the rod, you generated a static electric field. The electric field associated with radio waves differs from the electrostatic field only in that it varies in time; this is not unlike the difference between ac and dc.

We know, from the principles of continuity, that the current leaving the signal source \( E \) at the right in fig. 3 is exactly equal to the current returning at the left. The current flows through the resistor and the inductor, but what happens at the capacitor? There is no movement of electrons through the dielectric separating the plates of the capacitor, so there appears to be a discontinuity in the current flow. However, from our experience in low-frequency ac circuits, we know that current apparently flows through the capacitor.

displacement current

This difficulty was recognized many years ago and was straightened out by inventing a new kind of current called displacement current. Actually, modern physicists do not feel that displacement current is so much a current as did the early researchers; nevertheless the concept is still valid. In fact, since displacement current produces the same effects as actual conduction current in describing this phenomenon.

The displacement current between capacitor plates is a function of the changing electromagnetic field between the plates (fig. 4). In elementary static-electricity theory, displacement current doesn't exist because the electrostatic field doesn't vary with time.
The magnetic field surrounding a current-carrying conductor may be expressed by

\[ H = \frac{I}{2\pi r} \quad (1) \]

where \( H \) is the magnetic flux density at a distance \( r \) from a wire carrying a current \( I \) (fig. 5).

Michael Faraday (1791-1867) discovered that an electromotive force \( E \) could be generated by a magnetic field cutting the current-carrying conductor:

\[ E = \frac{H}{t} \quad (2) \]

where the induced voltage \( E \) is proportional to the magnitude of change in the magnetic flux and inversely proportional to the time in which the flux changes. *

From (1) it can be seen that the induced voltage \( E \) will increase with either a larger or faster change in magnetic flux density \( H \). In other words, if the flux change is held constant, the induced voltage will increase with the frequency of the magnetic-flux change.

**the electromagnetic field**

Note that no mention is made of either conductor size or material in either of the above equations. If the size of the conductor were gradually reduced step by step, the induced voltage would remain the same, because the law states nothing to the contrary. In fact, the size of the wire may be reduced until there is no wire, but there will still be an induced voltage across the space that was occupied by the wire.

The voltage induced across space by the changing magnetic flux is in the form of an electric field. This field causes the flow of displacement current; the displacement current generates a magnetic field in direct proportion to its intensity. The electric and magnetic fields then are complementary, with one generating the other as they move through space at the speed of light. The combined effect of electric and magnetic flux form an electromagnetic field.

The electromagnetic field may be represented as in fig. 6, where the electric and magnetic lines of force are perpendicular to each other and mutually perpendicular to the direction of propagation. Although the electric and magnetic fields are represented by lines of force, separate \( E \) and \( H \) lines don't exist in space; rather a kind of electric or magnetic tension exists that's directly proportional to the intensity of the flux. That is, more lines of force are used to illustrate a strong field than a weak one.

**the microwave domain**

The fact that a changing magnetic field induces a voltage across space is the concept needed to understand microwave circuits. In other words, at ultra-high frequencies the current flows not only in conductors; it may flow as displacement current between points in space. In a sense there is still a circuit, but the paths are no longer well defined.

One of the outstanding events in the history of microwave theory was the recognition of the similarities between the effects of different electromagnetic field configurations and those in inductive, capacitive, and resistive elements — the circuit components familiar at the lower frequencies.

When the basic circuit elements are viewed from the fundamental concept of energy, it becomes obvious that the
energy of an inductor is always stored in a magnetic field, and the energy of a capacitor is always stored in an electric field. Therefore, any microwave component that stores energy by the virtue of an electric field is regarded as having capacitance. Conversely, any component storing energy in a magnetic field is considered to possess an equivalent inductance. When microwave energy is dissipated in terms of heat, the effect is similar to a resistive component in a low-frequency system.

With certain reservations, the impedance associated with a microwave circuit may be related to the R, L, and C elements in exactly the same way as at the lower frequencies. In a low-frequency circuit, where the wavelength is many times larger than that of the individual circuit elements, no anomaly exists. However, in a microwave system, the wavelength is comparable to each of the circuit elements, and the magnitude of the R, L, and C components is dependent upon wavelength. Therefore, an inductive or capacitive value may be assigned to a microwave component only when the frequency is held constant. However, in practical circuits where bandwidth is relatively narrow, this concept allows one to use his knowledge of low-frequency ac theory to increase his understanding of microwave circuit with a minimum of error.

bibliography
### 2-M Class "C" Amplifier

**Model FM-3-30**
- 1 to 3.5 watts input gives 17 to 30 watts output typically.
- Automatically T/R switching.
- Size: 7" x 5" x 3"
- MOBILE OPERATION
- 13.5 V.D.C.
- Input: 1 to 3.5 watts.
- Output: Typically 20 watts out for 1 in.
- Only $89.95

**Model FM-7**
- 13.5 V.D.C.
- 1 to 3.5 watts input.
- 4 to 12 watts output.
- Automatically T/R switching.
- Size: 5⅛" x 3" x 2½"
- Only $49.95

**Model FM-25**
- 13.5 V.D.C.
- 4 to 12 watts input.
- 12 to 30 watts output.
- TYPICALLY 25 OUT FOR 10 IN.
- AUTOMATIC T/R SWITCHING
- SIZE: 5⅛" x 3" x 2½"
- Only $69.95

**Model FM-10-50**
- 13.5 V.D.C.
- 4 to 12 watts input.
- 20 to 50 watts output.
- AUTOMATIC T/R SWITCHING
- SIZE: 7" x 5" x 3"
- Only $119.95

### Solid-State Electronic Keyer

**Model KE-1**
- FEATURES
  - 4 to 60 W.P.M. operation.
  - Two variable speed ranges.
  - Automatic operation.
  - Semi-automatic operation (bug).
  - Hold (tune) function.
  - Reed relay output (10W).
  - 115V operation.
  - Instructions for use from external regulated 3 V.D.C. source.
- Size: 4½" x 4½" x 2½"
- Low Low Price $54.95

### Other Products

- 2M Preamps — 12 V.D.C. operation — 13 dB gain — 3.5 dB noise.
- 2" x 2½" — No case — Mosfet with diode protection — With instructions.
- $12.95

### Terms

- 90 Day Parts and Labor Warranty on all products.
- Send check or money order to: (Dealer inquiries invited).
- We will ship UPS postpaid on cash orders.
- C.O.D. orders accepted with 25% deposit.

The highly stable vfo described in this article has evolved over several years. It features sufficient output for any mixer configuration, is very solid, has small size and exhibits excellent spectral purity. It tunes the frequency range from 5.0 to 5.5 MHz with ±150 kHz overlap.

The basic oscillator circuit is the inherently stable Seiler type. In the Seiler circuit the transistor and tank circuit are very lightly loaded, resulting in excellent frequency stability. The tuning capacitor is a small type used in fm broadcast receivers; it has a built-in 3:1 spring-loaded drive mechanism. With the dual tuning capacitors used in this design (see fig. 1) either one of two output frequencies may be selected by relay K1.

The vfo circuit is housed in a very solidly built aluminum box approximately 4 inches long, 2½ inches wide and 3/16-inch thick. This construction provides a high thermal integration constant so ambient temperature variations have little effect upon the oscillator frequency.

Circuit

In the circuit in fig. 1 the lower limit of the variable tuning capacitance is approximated by

\[ C = \frac{\Delta C}{\left(\frac{f - \Delta f}{f}\right)^2 - 1} \]

where C is the required minimum tuning
Capacitors marked with asterisk are mica; NPO capacitors are N750 ceramic types.

**C1, C2**  
3-section 3.2 to 18.5 pF variable, parallel connected

**L1**  
7.5 μH, 13.5 turns 0.5 mm enameled (no. 24) in 2 layers on ferrite pot core

**L2**  
30 turns 0.2 mm enameled (no. 34), honeycomb wound, 4 mm (0.16 inch) long, on 65 mm (1/4 inch) slug-tuned form

**L3**  
30 turns 0.2 enameled (no. 34), honeycomb wound, 4 mm (0.16 inch) long, on same form as L2 (see text)

---

fig. 1. Schematic diagram of the high-stability vfo. One of two output frequencies is selected by K1. If K1 is controlled by a multivibrator two receiving channels may be monitored at the same time.

---

Capacitance, f is the upper frequency limit, Δf is the frequency change and ΔC is the total tuning capacitance variation.

The unused tuning capacitor has some affect upon the output frequency although it is isolated by the small capacitance (about 4 pF) of the open relay contacts. The greatest effect occurs at the upper frequency limit when the main tuning capacitor is at minimum capacitance. This effect can be minimized by making the minimum tuning capacitance as large as possible by sharing the fixed capacitors in the tuned circuit.

If you already have a stable regulated 12-volt supply you can eliminate the 1N756A zener diode and the 180-ohm resistor. Power consumption is 35 mA with the zener circuit, 25 mA without it.

Use a fast, reliable relay to switch the tuning capacitors. The rf voltage at this point in the circuit is 30 to 40 V p-p. A high-quality reed relay is recommended. The diode across the relay coil eliminates the negative voltage transient when the coil is de-energized.

If you want two-channel control for your receiver use a multivibrator circuit to control the relay. Try a multivibrator frequency between 10 and 300 Hz. In addition to the two desired channels there will be adjacent sidebands with spacings equal to the multivibrator frequency.

In a circuit of this type the vfo signal is usually taken from the source of the oscillator fet. On a good oscilloscope the waveform at this point is very close to a
true sinusoid. However, a check with a spectrum analyzer will reveal that the second harmonic is only 20 dB down. Since the output signal should be as clear of harmonics as possible, in fig. 1 the oscillator output signal is taken from the frequency-determining circuit. At this point in the circuit the second harmonic is more than 50 dB down.

The vfo input signal to gate 1 of the MPF121 amplifier should not be greater than 0.9 V p-p. The MPF121 is an inexpensive, zener-protected mosfet and will provide all the needed amplification with good isolation between input and output. The drain current of the MPF121 is set to 10 mA by selecting the source resistor; this current level results in maximum linearity.

The 47-ohm resistor in the drain circuit of the MPF121 prevents vhf parasitic oscillations. I found that the gate-1 lead inductance and drain lead inductance resonated with the 100 pF capacitors to form a tuned-drain, tuned-gate oscillator around 800 MHz. This parasitic oscillation is effectively damped by the 47-ohm resistor in series with the output tuned circuit.

Inductors L2 and L3 are both honeycomb wound. One of the coils may be moved along the coil form to control coupling. The output bandpass of this circuit should be tuned with a sweep generator to obtain optimum performance. Output from the sweep generator is terminated with a 50-ohm resistor and fed to gate 1 of the MPF121. The vfo output is connected to 50-ohm coax to the input of the sweep generator, terminated by a 75-ohm resistor. This is approximately a 30-ohm load. With this arrangement output is flat within 0.1 dB from 5.0 to 5.5 MHz; attenuation at 10 MHz is about 50 dB.

A hot-carrier diode ring mixer requires about 10 mW of rf injection, much more than other mixer arrangements. The output of this circuit is just sufficient. When aligning the vfo be careful not to overdrive the MPF121; 0.9 V p-p is enough. More drive will not increase the desired output signal but will produce considerably more harmonics.
The high-frequency vfo is built into a rugged aluminum chassis. Layout is shown in fig. 4.

**construction**

The high electrical stability of this circuit cannot be realized unless the actual physical construction is mechanically stable. The temperature delay through the 3/16-inch sides of the cast-aluminum chassis shown in the photos is about ten minutes.

For maximum rigidity the two tuning capacitors are screwed to the sides of the chassis. Distance between shafts is 75 mm (2-7/8 inches); therefore, two 70-mm (2-3/4-inch) dials can be used (see fig. 2).

The printed-circuit board shown in fig. 3 is soldered directly to feedthrough inserts and grounded in two places with metal straps. Both sides of the board are easily accessible.

If a ferrite core is used in L1, the relay should be placed as far away as possible. The magnetic field around the relay coil affects the ferrite; magnetic shielding may be necessary.

The gear drives to the tuning capacitors are left outside the aluminum chassis. I have not found a single reliable planetary drive mechanism; spring-loaded gears are preferred. A ratio of 10:1 is sufficient; this provides about 50 kHz per turn. I found a 36:1 drive from Semcoset in Germany which gives about 15 kHz per turn.
table 1. Operating characteristics of the high-stability vfo.

frequency range 4,850 to 5,650 MHz
frequency used 5,000 to 5,500 MHz
output level 1.9 V p-p ±0.5 dB into 35 ohms
stability 15 Hz per °C
5 Hz per volt (9 to 20 volts)
output open/short circuited 20 Hz difference
harmonic content more than 70 dB down
mechanical shock less than 100-Hz frequency change with several successive hard shocks
supply voltage 10 to 18 V, 12 V nominal
power consumption 35 mA (relay, 40 mA)
size 100 x 60 x 46 mm (3.9 x 2.4 x 1.5 inches)

summary

The complete operating specifications of this vfo are given in table 1. Several similar units have been built, and all exhibit the same operating characteristics.

This is by no means an exceptional device, but it is a good answer for the modern amateur. When using a hot-carrier diode ring mixer in a bilateral transceiver this vfo uses the minimum number of components for the features it provides.

fig. 5. Frequency drift characteristics of the vfo when turned on from a cold start.

adding
160-meter coverage
to the
HQ125 receiver

This simple modification should add rather than detract from the resale value of your HQ125. No metalwork surgery is required.

Although the Hammerlund HQ215 has a number of positions on the bandswitch for additional 200-kHz segment coverage on the various bands, the receiver's design does not permit such frequency ranges below approximately 3.4 MHz. After studying the problem of 160-meter coverage, the following relatively simple modification was devised. It can be accomplished with reasonable skill, without tearing apart any of the existing circuitry and without the need for drilling any of the metalwork.

An additional crystal is required to cover the range of 1.8 to 2.0 MHz. Crystals for several receivers modified by me were obtained from the International Crystal Manufacturing Company.* The appropriate pages of the Hammerlund manual were forwarded to International Crystal so the crystals would correlate and calibrate properly. The frequency of

*International Crystal Manufacturing Company, Inc., 10 North Lee, Oklahoma City, Oklahoma 73102.
the crystal required for this modification is 4.9550 MHz. The various fixed and trimmer capacitors called for at the end of the article should also be on hand when the modification is started.

Complete coverage of the 160-meter band is not possible with a single position of the band selector due to the relatively small value of available capacitance change compared to the large values to be added by this modification. Therefore, it is necessary to split the band segments into two segments of 100 kHz, each covered by separate positions (B and C) of the bandswitch, to obtain optimum sensitivity over the entire band. Tuning of the second oscillator stage, however, will cover the entire 160-meter band regardless of the setting of the bandswitch with respect to position B or C.

Two sections of instructions follow which will allow you to cover either segment as a complete operation, or, by completing both section, to cover the entire band.

It is assumed that the receiver to be modified is in normal working order and does not require service. Remove the top, bottom and the side panel nearest the bandswitch in accordance with the instructions in the HQ215 service manual. Note: The following procedures assume that the receiver is upside down on the workbench with the front panel closest to the operator.

1.8 to 1.9 MHz

Install a 4.9550-MHz crystal into position C (not B) of the crystal deck. Positions 5 and 6 of section D of switch S-101 should be shorted by soldering a short length of number-18 or 20 solid tinned wire across the switch tabs. Do not attempt to insert the wire into the eyelet holes, simply lay the wire on top of the tabs. Be sure that no solder droppings or bits of wire fall down into the receiver. Pins 5 and 6 of section D are on the wafer closest to the rear of the receiver, and in several units I have checked these pins have green and yellow wires.

Trimmer capacitor C127 (refer to figure 4-3 of the HQ215 manual) should be adjusted to its maximum capacity (maximum clockwise tension on the screw) but be sure to not apply so much tension as to strip the threads. When operating properly, it should be possible to hear a loud spurious signal between 3 and 5 kHz below 1800 kHz. This is a normal "birdie" for the frequency conversion scheme used in the HQ215. It may be necessary to parallel C127 with a 220-pF silver-mica capacitor if the resultant note at 1.8 MHz using the calibrate position is not clean. Readjust C127 to obtain the cleanest sounding marker signal.

Although the schematic in the manual shows trimmer capacitors C120, C125 and C130 connected to contact 6 of S101A, B and C, respectively, a physical examination of the bandswitch reveals that they are actually connected to terminal 5, with jumpers to 4 and 6. Very carefully cut the jumpers between terminals 5 and 6 of the three front (A, B and C) sections, leaving terminal 6 clean and ready for the additional padders to be installed. Extreme care must be used at this stage of the conversion to insure that the bandswitch is not damaged and that no solder droppings fall into the receiver. If this does happen, they should be shaken loose and removed completely before proceeding.

Next, prepare the three variable trimmers (310-700-pF, Electromotive type PC4215) as follows: For switch section A, wire a 1000-pF silver-mica capacitor across the variable trimmer. For switch section B, connect a 1500-pF across the trimmer, and for section C (the first mixer circuit) use a 1000-pF capacitor across the trimmer. The leads on the fixed capacitors should be carefully trimmed and wrapped around the tabs of the trimmers and soldered to hold the leads near the base of the tabs.

Before installing the new padders, place them in approximate position and note the spot on the grounding shield between switch sections where one side of the trimmer will anchor. Tin this area.
of the shield and then install the padders between the appropriate pins and the tinned spot on the shield. Be careful not to force the switch tabs out of their normal position so there will be no strain on the switch when this operation is completed.

One last operation is left. Install a 47-pF silver-mica capacitor from terminal 6 of S101B to terminal 6 of S101C. This completes the modification required to permit the rf tuned circuits to cover the range of approximately 1.8 MHz to 1.9 MHz, with the exception of alignment.

**1.9 to 2.0 MHz**

Prepare two 1220-pF capacitors by wiring a 1000-pF and a 220-pF silver-mica in parallel. Install one of these 1220-pF capacitors across C120 (switch section A) in Section 1. Install a 1500-pF silver-mica capacitor across C125 (switch section B) and the other 1220-pF unit across C130 (switch section C). Also, as in section 1, install a 47-pF silver-mica between terminal 5 of S101B and terminal 5 of S101C. This completes the required rework except for alignment.

Before continuing with the alignment it's a good idea to be sure no loose bits of wire or solder are inside the receiver, and...
that all other bands still work properly. Make necessary repairs by correcting any wiring errors, etc.

alignment

The calibrate function of the receiver may be used in lieu of a signal generator. Just remember to keep the rf gain control set so the S-Meter reads somewhere between S-5 and S-9. Final touch-up may best be performed "on-the-air." The receiver agc switch should be set to fast agc.

Set the preselector tuning knob to 9 and the main tuning dial to 0. Set the bandswitch to C; this should represent 1.8 MHz. Turning the calibrate switch on and off should result in a signal easily identified. Leave the calibrate switch on, and by using the S-meter adjust the three trimmers just installed in section 1 for maximum reading. Repeat the adjustment two or three times to be sure you have the correct adjustment. Move the tuning dial to 100, which represents 1.9 MHz, turn the preselector knob to 1, and noting the positions of each of the three trimmers carefully touch up the adjustments and again note the position of the trimmers. There should be very little difference between the two settings. Leave the trimmers set to the center of the two settings.

If you do not hear the 100-kHz marker tone at 100 on the dial, your crystal may not be oscillating on the proper frequency. Recheck the wiring of the rear section of S101 and readjust the trimmer capacitor (C127). This completes the adjustment of the 1.8-1.9 MHz segment of the 160-meter band.

The bandswitch should now be placed in position B and the main tuning dial to 200, which represents 2.0 MHz, and the preselector tuning knob to 1. Again, you should hear the calibrate marker signal, and it should sound clean — no hum or roughness. Peak trimmer capacitors C120, C125 and C130 for maximum S-Meter reading, repeating two or three times to be sure of the best settings and taking into account the precautions mentioned previously regarding overloading the receiver. Set the main tuning dial to 100 again, set the preselector knob to 9 and follow the procedure mentioned above to optimize the trimmer settings.

If desired, you may simply peak up the trimmers "on-the-air" for those portions of the band which you prefer, although very little difference in performance has been noted on the several receivers with which I have had experience. It should be remembered that moving the bandswitch from position C to position B will not affect the incoming signal tuning, as far as the frequency is concerned, but only from the viewpoint sensitivity. Extremely strong signals will be heard even though the preselector is not tuned to resonance with the incoming signal, but weak signals will be lost. There will, of course, be some overlap between the two segments near the 1.9-MHz portion of the band.

conclusion

This modification results in a receiver capable of good performance on 160 meters, and will provide all the sensitivity that can normally be used in most locations. Some operators may feel that an external preamplifier might be useful, but this is true only if the receiving location is extremely quiet and atmospheric noise is very low.

The sensitivity of the receiver I modified measured better than a half microvolt for a 10-dB signal-plus-noise-to-noise ratio. This was on both the CW and ssb modes of operation. This sensitivity should be sufficient for even serious DXing on 160 meters.

With a little study and a few easily obtainable parts this entire project can easily be completed in one evening's time and adds greatly to the usefulness and the pleasure of using the HQ215. I would like to thank George Faatz, K4KH, who proofread these instructions while performing the modification on his own HQ215.

compact
tone-burst keyer
for fm repeaters

As two-meter fm repeaters multiply across the country, more of the groups operating them may be expected to turn to some form of tone-guarded input, not to exclude non-members, but simply to eliminate accidental sporadic keying of the system by stations using the same input frequency in another area.

With the decision to install a 2000-Hz single-tone decoder on the 146.34 MHz input to the WB8CQR repeater this past spring, I started looking for a replacement for the tone generator I built a year ago for my occasional visits to Chicago and other areas with controlled-access repeaters. That unit, a Colpitts-type transistor oscillator using an 88-mH toroid, keyed manually with a push button, worked perfectly but was bulky and awkward.

What I sought was an oscillator that would: key automatically with the push-to-talk circuit, provide a frequency-stable tone on at least two switch-selected frequencies, be small enough to mount inside one of the compact transistorized transceivers, such as my Varitronics IC-2F, and draw minimum current to avoid undue drain on a portable's power supply. The answer was found in a Motorola application bulletin.¹ It is a saw-tooth generator using two diodes and a capacitor, switched by a modified monostable multivibrator which can be triggered by the microphone push-to-talk circuit. The circuit is shown in fig. 1.
circuit operation

Operation is as follows: When the PTT switch is open (the receive condition) the microphone PTT circuit is ungrounded and a positive voltage appears at terminal 3. Applied to the base of Q1 through diodes CR4 and CR3, this voltage turns Q1 off, which turns Q2 on. It also charges C1.

With Q2 on, approximately 12 volts is applied to CR2, a Motorola field-effect diode (also known as a current-limiting diode or current Zener). Basically this device is a field-effect transistor with the control gate and source internally connected to the substrate; it has the interesting characteristic that when reverse biased it will conduct an almost constant current regardless of the applied voltage.

Increasing the voltage across them and diode CR1. Diode CR1 is a four-layer or pnpn diode. It has two stable states: off, in which it exhibits resistance of a megohm or more, and on, in which its resistance is only a few ohms. Transition from off to on is controlled by the voltage applied; as the capacitors charge the diode remains off until its breakover voltage is reached, at which time it turns on, discharges the capacitors practically instantaneously and turns off again. The frequency of oscillation is thus determined by three factors: The current conducted by CR2, the value of the capacitors and the breakover voltage of CR1. A vernier adjustment is obtained by connecting a resistor across the capacitors to bleed off part of the charging current.

The oscillator runs constantly as long as the PTT switch is open and positive voltage is present at terminal 3. When the transmitter is keyed by closing the PTT switch and grounding terminal 3, the oscillator continues to run, and a tone is transmitted until capacitor C1 discharges.

This current ranges from 0.22 mA for the 1N5283 to 1.60 mA for the 1N5303; the circuit shown uses a 1N5299, rated at 1.20 mA ±10%.

The constant current through CR2 charges the capacitors at a constant rate, as the PTT switch is open and positive voltage is present at terminal 3. When the transmitter is keyed by closing the PTT switch and grounding terminal 3, the oscillator continues to run, and a tone is transmitted until capacitor C1 discharges.

fig. 1. Simple tone-burst oscillator circuit provides tones of 1800 and 2000 Hz. Diodes CR3 and CR4 are general-purpose diodes. R1 and C1 are selected for desired burst duration; for value of C2, C3, R2 and R3 see text.
C1 and R1 thus control the burst duration; values of 30 µF and 100k ohms give about ¾ second. When C1 is discharged, Q1 turns on, Q2 is turned off, the voltage draws less than 2 mA when the PTT switch is closed. It is very compact; the actual size of the circuit board shown in fig. 2 is ¾ by 1¼ inch, and the clearance

![Circuit Diagram](image)

*fig. 3. Most simple tone-burst oscillator can be built into a microphone. The circuit is powered by a charged 350-µF capacitor; as the capacitor discharges, the tone drifts downward. Capacitor C1 is approximately 0.02 µF (select to desired frequency).

at CR2 is reduced to approximately 1 volt. The oscillator stops until the positive voltage is restored to the base of Q1 by release of the PTT switch.

![Circuit Diagram](image)

*fig. 2. Full-size circuit-board layout for the compact tone-burst oscillator.

The unit draws approximately 6 mA with the oscillator running (1.2 mA through CR2 and the rest through the 2.2k load resistor connected to Q2). It required above the board is only 3/8 inch.*

**construction**

For most compact assembly all resistors for which numerical values are shown should be installed first, as close to the board as possible. Capacitors fit between and overlap the resistors. Transistors and diodes are installed in a second layer, with leads extending down to the board between the other components.

With all components in place except C2, C3, R2 and R3, the burst duration should be checked by observing the voltage at the collector of Q2 as the PTT

*Printed-circuit boards are available from the author for $2.50, postpaid, in the United States and Canada.
The oscillator frequency adjustment must be made experimentally using a counter or other standard, as the capacitors, diodes and resistors all have 10% tolerance and the allowable margin of error in most repeater tone decoders is on the order of 0.5%. Select C2 and R2 to give the desired high tone (2000 Hz in the unit shown here); then select R3 to give the low note. Installation of C3 is usually unnecessary.

The circuit has been tested in a variety of equipment with the WB8CQR single-tone decoder and keys the repeater with less than 2-kHz deviation on the transmitted signal. Deviation can be set at whatever level is desired by changing resistor values in the output voltage divider. Frequency is comparatively stable for a power supply voltage range between 12.5 and 15 volts. There is some drift with temperature change; if it is excessive, try new resistors and capacitors in the oscillator. I have found a few that were much worse than average and resulted in unsatisfactory performance of the unit in which they were installed.

The same oscillator circuit was used to make a miniature tone generator that could be completely contained in the mobile microphone case. The circuit is shown in fig. 3. Power for the oscillator is drawn from a 350-μF electrolytic capacitor charged from the PTT circuit. It had only one fault; the tone tailed off in frequency as the capacitor discharged, and the signal swept from 2000 Hz to below 1800 Hz before the oscillator cut off. This circuit is also sensitive to lead lengths in the capacitor network. C1 must be selected in its working location. If you want a universal repeater keyer, this will do it! If you value the opinion of your friends, however, I recommend the version shown in fig. 1.

reference
Fast break-in is a must for traffic nets and contests — here’s a circuit using solid-state switching for quiet operation.

Several simple break-in circuits for CW have been tried at my station with varying degrees of success. Some seemed to work fairly well, but key clicks and thumps were difficult to eliminate. Mechanical relays for switching increased the room noise level considerably. When the break-in system is too noisy, one tends to send faster or shorten character spacing to hold the relays closed, thus reducing noise. This, of course, defeats the purpose of break-in, which is to allow signals to be heard between letters while sending. Other circuits I have not yet tried seemed far too complicated for simple break-in.

**Preliminary Steps**

Before attempting to use any break-in system, the receiver and transmitter should be tested to determine if they will perform properly under fast switching conditions. In full break-in, the exciter and final-amplifier plate voltages are on and the tubes biased to cut-off or beyond. This condition could cause diode noise in the receiver and should be corrected.* The receiver should be tested for its willingness to cooperate with the break-in system by connecting a variable voltage, 0-75 volts, to the AVC line. With bias connected key the transmitter. If a clean signal is heard without key clicks or thumps and the gain can be adjusted to the desired level, full break-in circuitry can be added with no difficulty.

**Break-in Circuit**

A separate receiving antenna is used at my station. In the circuit shown in fig. 1 a switch, SW1, is used to change modes. The circuit is designed to be used with grid-block keying, and the -75 V is obtained from the transmitter bias supply. A separate supply could be used, however.

*Although this problem can be caused by tube-type rectifiers in the transmitter high-voltage supply (due to contact potential, leakage paths, etc), a common cause of receiver noise under the conditions stated by the author is improper bias and neutralization of the final amplifier tubes. editor.
When the four-pole, three-position switch is in the break-in position, SW1D connects the receiver to the receiving antenna, and the transmitting antenna input is grounded at this point through SW1C. Capacitors C3, C4 and diode D2 form a solid-state switch, which is quite effective. This circuit is an improvement over simply shorting the antenna to ground and is more effective than a spdt relay.

SW1B connects the key or electronic keyer to the base of Q1, an npn silicon transistor. With -75 V connected to the emitter and the base resistor, R1, returned to ground through the key, Q1 conducts heavily, and the -75 V appears at the collector and at the top of R3. Since R3 is connected in series with D2, D2 also conducts heavily, grounding the antenna input to the receiver. A variable bias voltage of 0.6 to -75 V is now available at the slider arm of R3 and is connected to the receiver avc line through D1. D1 prevents shorting the avc line during key-up conditions.

SW1A turns the transmitter B+ on in both break-in and normal transmit positions. In the transmit position, Q1 conducts and the receiver may be used for monitoring but will remain off until the switch is returned to receive or break-in. In the receive position, the receiver operates with the transmitting antenna, but the solid-state switch is still in the circuit.

**Construction**

The entire circuit is built in a 2 x 3 x 5-inch minibox. Phonograph jacks and plugs are used for all connections. Shielded leads are used. The transistor I used is a Motorola RV video amplifier type M4843. Television receivers, especially color sets, use transistors with rather high voltage ratings. Some horizontal sweep power transistors operate with peak voltages as high as 800 volts. In this circuit any good quality npn transistor of the required voltage rating may be used, but it would be a good idea to check for leakage before closing the box. No voltage should be present on the collector with the key open in the receive or break-in switch position.

I've been using the circuit for a few months and have been pleased with the results. Received signals can be heard between letters at reasonable code speeds. I use the circuit with an unmodified 75A4 receiver on fast avc. The receiving antenna consists of about 25 feet of wire and works quite well except for signals below S4 or S5. A better receiving antenna will be installed soon, which should improve circuit performance.

---

**Fig. 1.** CW break-in circuit using solid-state switch for stations with separate transmitting and receiving antennas. Design is for grid-block keying systems.
Low-pass filters have been designed and built for many years according to the conventional formulas found in various handbooks. Such formulas are based on so-called image-reflection design, and a filter built according to these formulas consists of one to three constant-k center sections and two m-derived terminating half sections. The filter is usually designed for use with a 52- or 72-ohm coaxial line. The attenuation characteristics of such a filter are valid only if the filter is used with the type of line for which it is designed and if that line operates near unity swr. In recent years, filter design has improved because of an interest on the part of military and other communications-equipment designers to achieve superior filter performance at minimum cost.

This article presents construction data on low-pass filters for 10 and 15 meters which have been designed according to latest available techniques. Either filter may be built from readily available parts for any power to 2 kW PEP.

The advantage of filters designed according to modern techniques is the superior harmonic attenuation obtained using fewer components. For example, the filters described here use only 3 coils; yet the harmonic attenuation is as good or better than that of filters using 5-6 coils. Using fewer coils may not sound like an advantage in theory, but it means a great deal in practice. Unlike capacitors, coils in a low-pass filter must either be shielded or oriented to prevent mutual coupling, which degrades filter performance.

Building a really effective low-pass filter that gives a true 50-70 dB harmonic attenuation, using conventional design techniques, often presents a mechanical problem because of the shielding required between filter elements. Modern filters, on the other hand, are not only easier to build to achieve the same performance level but are less critical as to construction techniques. The latter assertion can’t be proved from theory, but it certainly seems to be the case as far as I’ve been able to observe when building various filters.

design characteristics

The filter design is shown in fig. 1. It’s
intended for insertion in a coaxial transmission line of 52-72 ohms (design optimized for 52 ohms), either between an exciter and a linear amplifier or between a linear amplifier and antenna. The three-section design uses a combination of parallel- and series-resonant circuits. The design can’t be reduced to only using the most elaborate and expensive construction techniques. A paper design may achieve almost an infinite harmonic attenuation level, and, indeed, this is one of the dangers of conventional filter design where it appears that one could add constant-k sections almost endlessly. In short, the design shown in fig. 1

![fig. 1. General arrangement of filter. Refer to table 1 for constants.](image)

two coils, because all circuit elements are interdependent. Built as shown, however, the filter yields outstanding harmonic attenuation without involved construction details.

The filter design has a cut-off frequency up to which the filter will pass radio frequencies with minimum attenuation. Beyond the cut-off frequency, the attenuation increases rapidly with frequency until it reaches the first peak of maximum attenuation. In the specific designs shown later, this latter frequency is from 1.5 to 2 times that of the cut-off frequency. At this first attenuation peak, the attenuation is theoretically at least 70-90 dB as compared to the level below the cut-off frequency. The attenuation at all higher frequencies is at least 70 dB, with a number of peaks providing even higher attenuation.

practical considerations

One can design filters that achieve theoretically even greater harmonic attenuation. However, the practical realization of levels greater than 70-90 dB with simple construction materials and techniques is illusory. The practical limit for filter elements seems to be about 120 dB, and this has been achieved only in designs represents the practical limit for a filter that will work well.

15-meter model

The first filter to be described is for use with transmitters operating at 21 MHz or below. Component values are shown in table 1. All may be achieved with readily available capacitor values. The 15-meter filter attenuation begins about 22-23 MHz and reaches its first peak (about 60 dB) at 40-42 MHz (fig. 2), which provides good harmonic attenuation in the i-f range of most TV sets. This feature is, in fact, the reason for developing a 15-meter filter. A low-pass filter that begins cutoff above 21 MHz provides excellent attenuation at TV intermediate frequencies as well as at the beginning of the vhf TV channels. Another consideration is that, as the sunspot count decreases in the coming years, there will be less activity on 10 meters.

Many cases of TVI can be eliminated by this means where TV i-f interference has been a problem. In a few instances, even problems with nearby CB installations can be avoided with such a filter since its attenuation at frequencies above the 21-MHz band will be effective for both reception as well as transmission.
10-meter model

The second filter has a cut-off frequency of about 30 MHz. An attempt was made to design a filter that offers significant protection at TV-receiver i-fs using filter elements within reasonable tolerances. Circuit values for this filter are also shown in table 1. The first maximum attenuation peak occurs about 60 MHz. However, the slope after the cut-off frequency is quite steep, and significant attenuation begins at 40 MHz. Again, the filter was designed for available capacitor values.

capacitors

Mica capacitors should be used. The physically smallest 500-vdcw mica is inexpensive and may be used for filters operating at the 300-watt PEP output level (15 meters) and at 100-150 watts for 10 meters.

These capacitors therefore, are suitable for a filter between a 100-watt (nominal) output exciter and a high-power linear. Such a filter is often overlooked in TVI problems because of the expense of a commercial filter for both the exciter-final link and the final-antenna link. However, a filter between exciter and final is useful in attenuating harmonic radiation, which causes TVI, because the exciter will have some harmonic output.

Larger mica capacitors may be used for filters for any desired power level. Molded mica capacitors rated at 1500 volts dc working are useful in filters operating to 1-kW PEP output. Type CM-15 mica capacitors, rated at 2500 or 5000 vdcw, may be used with even the most efficient 2-kW PEP linear.

construction

Filter construction is easy since only three coils are used, which should be mutually shielded. The coils can be made from Air-Dux or B&W stock, or wound from tinned copper wire. The small sizes of coil stock are fine for transmitter output powers up to 500 watts PEP. Coils for higher power should be wound with no. 10 or 12 tinned copper wire. The capacitor values in table 1 should be adhered to.

The photo shows a filter using low-voltage mica capacitors. Brass sheet stock forms an enclosure 5½ inches long by 2 inches square. Equally spaced dividers separate filter sections, and simple feedthrough insulators are used between sections.

Brass sheet has several advantages. The material is easy to work. The sides of the enclosure as well as the dividers can be soldered. The cover can also be completely solder-sealed. Such shielding efforts really help, particularly when trying to combat TVI in the uhf ranges where the screwdriver assembly of conventional filters allows rf leakage.

results

The attenuation characteristics of the filters I built are shown in fig. 2. The 15-meter filter slope reaches an attenua-
tion peak at the TV i-f range. The equipment I used to check the filter was of good laboratory quality, which the average amateur doesn’t have. Nonetheless, the instrumentation wasn’t capable of making accurate attenuation measurements in the vhf range beyond -60 to -70 dB. The curves of fig. 2, therefore, are conservative.

A careful sweep of the vhf range disclosed no frequency where filter attenuation fell below -60 to -70 dB. This result included the effects of the phono-type connectors used in the filter construction. The attenuation of the filter in the pass-band region varied between .1 and about .25 dB but never exceeded the latter value. When inserted in a matched 52-ohm transmission line, the filter produced a worstcase swr of 1.1.

**Conclusion**

I claim no credit for the original design of the filter. That belongs to a number of scientists. The purpose of this article is to present two selected and truly practical low-pass filters that satisfy requirements for any 80-10 meter amateur installation.

A point that should again be emphasized is that the filters must include all the sections to be effective. You can’t eliminate any section without completely changing the filter’s attenuation characteristic.
threshold-gate/limiter
for

cw reception

Solid-state diodes
in a simple
and effective
circuit to reduce
filter ringing

A disadvantage of audio filters and Q multipliers is their ringing effect on received CW signals. This ringing is caused by the shaping effect introduced in the audio signal by the filter or Q multiplier, namely, rounding and lengthening, respectively, of the signal leading and trailing edge. A method of reducing this distortion is to introduce a later distortion that sharpens and shortens the signal.

threshold gating

A characteristic of solid-state diodes, i.e., their ability of not conducting in the forward direction until a critical voltage is reached, can be used to decrease ringing and background noise as well. Fig. 1 shows how a pair of diodes can be used to counteract ringing by providing a threshold-gating effect. The circuit has two additional features— it eliminates background noise below threshold level and provides single-signal reception of all signals with audio images falling below threshold. Further sharpening can be accomplished with a second set of diodes having a higher knee voltage, which operate as limiters. The effect of the combina-

fig. 1. Threshold-gating. Input waveform represents ringing effect of high-Q filtering; shaded parts represent output of threshold-gating circuit. Note elimination of background noise and reduction of ringing.
tion is shown in fig. 2 and can be described as a window-effect. The limiting diodes also prevent blasting by loud signals and, as shown in fig. 2, materially reduce the effects of signal fading.

A criticism of the threshold-gating/limiting circuit is that it severely distorts any audio tone passing through its intensity window. This is a valid criticism, and such distortion occurs when the circuit is used without prior high-Q filtering—the tone sounds raspy or scratchy. However, with the introduction of high-Q filtering the tone changes to a rather pleasant sound. Best results were observed when both Q multiplier and audio filter were used. It can be readily demonstrated that high-Q filtering and threshold-gating/limiting are effective in combination.

practical circuit

A practical circuit appears in fig. 3. Diodes may be selected from commercially available devices. In this case, I found that the emitter-base junction of a 2N414 made a good threshold diode, while the 1N54A performed well as a limiter. A switch was included so that the threshold-gating/limiting effect could be disabled for receiver tuning and when a signal quickly drops below threshold. A foot switch was convenient for this function. Note that the receiver output is not properly terminated. The problem here is the possibility of abnormally high voltages in the receiver output circuit causing damage to components. However, the limiting diodes reduce this possibility by clamping the output when high-level signals are received. The circuit has been used with vacuum-tube receivers without adverse effect. Although low-impedance earphones are indicated, high-impedance earphones may be used. These may be substituted directly, but it's preferable to use a matching transformer such as a vacuum-tube audio output transformer.

With high-Q filtering, the circuit provides the unique experience of being able to tune across a CW band and hear signals of approximately equal amplitude and tone drop in and out of a noiseless background. All signals tend to sound alike in terms of keying characteristics, as the combination of high-Q filtering and threshold-gating/limiting tends to eliminate individual differences. Most signals seem to be improved by the process. The circuit can be built into the cord of a headset.
Are 144 channel possible in an FM 2

Yes! In the new Swan FM 1210-A.

*Swan adds another dimension to 2 meter FM operation. Now with Swan's new independent switching for transmit and receive tuning (shown at right), combined with capacity for 12 receive and 12 transmit crystals, the FM 1210-A provides the capability for 144 channel combinations. With this wide selection of channels, crowded frequencies and unwanted QRM are virtually eliminated.

Selectivity has been greatly improved with the addition of our 16.9 mc crystal lattice filter that provides substantially greater rejection of adjacent channel interference. Extensive testing has shown that the new Swan 1210-A has selectivity equal to any 2 meter transceiver on the market, at any price.

The power of the FM 1210-A is rated at 10 watts output which, with the proper antenna, provides you with reliable communications. The output transistor is protected against damage from an improper load by an automatic protection circuit.

The Swan FM-2X
10 Watts, 12 Channels... Your best value!
Features automatic protection of the output transistor, and individual trimmers on each transmit and receive crystal. Its compact size makes it easy to install under the dash of your automobile, or use it with its attachable AC power supply in your ham shack. Everything you need is included at one low price: microphone, built-in speaker, AC and DC operation, and our quick disconnect mobile mounting bracket.

Each crystal has its own trimmer capacitor for exact frequency adjustment. In addition, the FM-1210-A is the ONLY 2 meter transceiver to provide a crystal oven for superior stability on those cold mornings.

Receiver audio to internal speaker is rated at 2 watts, almost twice that of most other 2 meter units, for loud clear reception of the station you are working. Provision has been made for the addition of an external speaker, and there is external keying for an amplifier.

Another exclusive and practical feature is the heavy-duty pedestal type AC power supply that is included in the purchase price. This new feature provides for compact base station efficiency and performance.

The Swan FM-2X

FM-2X SPECIFICATIONS

General
- Frequency coverage 144-148 mc.
- Number of channels: 12.
- Crystals installed for 3 channels as follows: Channel 1: transmit and receive 146.94 mc; Channel 2: transmit 146.34, receive 146.94 mc; Channel 3: transmit 146.34, receive 146.76 mc.
- Modulation: frequency modulation (phase type).
- Transmitter control: push to talk on microphone.
- Power source: AC 117 volts 50-60 cycles, DC 13.5 volts ± 10%.
- Dimensions: 8 1/4" x 7" x 3 1/2".
- Weight: 8 lbs.
- Furnished with unit: dynamic microphone, antenna connector plug, spare fuses and lamps, AC power supply, DC power cord with fuse holder.

Transmitter
- Fully solid state.
- RF power output 10 watts nominal.
- Frequency deviation adjustable to ± 15 kc; factory adjusted to approximately 5 kc.
- Frequency stability: ± 0.001%.
- Spurious radiation: -60 db below carrier.
- Frequency multiplication: 12 times.

Receiver
- Circuitry: crystal controlled double conversion superheterodyne.
- Input impedance: 50 to 75 ohms.
- Intermediate frequencies: 10.7 mc and 455 kc.
- Sensitivity: 0.5 uv for 20 db quieting, 0.5 uv for 12 db SINAD.
- Intermodulation: more than 50 db down.
- Audio output: 1 watt to internal speaker.

January 1972
combinations* meter transceiver?

FM 1210-A SPECIFICATIONS

- Frequency coverage 144-148 mc.
- Number of channels: 144 (12 rcv, 12 xmt, independent switching).
- 8 crystals are included as follows: TRANSMIT: 146.22, 146.34, 146.76, 146.94.
- RECEIVE: 146.28, 146.88, 146.76, 146.94.
- Modulation: frequency modulation (phase type).
- Transmitter control: push to talk on microphone.
- Power source: AC 117 volts 50-60 cycles, DC 13.5 volts ±10%.
- Dimensions: 8½" x 7" x 3".
- Weight: 8½ lbs.
- Furnished with unit: dynamic microphone, antenna connector plug, spare fuses and lamps, AC power supply, DC power cord, and mobile mounting bracket.

Transmitter
- Fully solid state, no tubes.
- RF output power: 10 watts nominal.
- Frequency deviation: phase type, factory adjusted to 5 kHz.
- Frequency stability: ±0.001%, -30° to +50°C, oven controlled.

As little as $10 per mo. on Swan's new Revolving Credit Service
$26 down, $10 mo. on unpaid balance. Annual percentage rate 18%.

100% SATISFACTION GUARANTEED
If you are not 100% satisfied with the Swan 1210-A 2 meter FM Transceiver, return it to the factory and the full purchase price will be refunded to you by return mail.

Gentlemen:
Please send me the following:
☐ Your 1972 Swan Catalog.
☐ Model 1210-A 2 meter FM Transceiver.
☐ Model FM-2X 2 meter FM Transceiver.

If you're planning to build equipment for use at vhf, the following suggestions will be helpful in selecting values of small capacitors for rf bypassing.

Above the self-resonant frequency of a capacitor an inductive component appears that can degrade the effectiveness of the capacitor as an rf-bypassing element. At frequencies near 100 MHz the problem is compounded when equipment is built on PC boards.

Suggestions for choosing the correct bypass capacitor in vhf circuits on PC boards

The self-resonant frequency is often ignored by many amateurs. To them, a capacitor provides ac coupling, ac bypassing, and dc blocking. Many also believe that the larger the capacitor, the better it will bypass high frequencies. The fallacy in these assumptions will become apparent in the following discussion.

Consider fig. 1. At A is a “perfect” capacitor. It has zero lead length, zero electrode dimensions, and a lossless dielectric. However, when plates are added to the “perfect” capacitor, and leads are added to the plates, a certain amount of inductance is introduced, as shown in B. The inductance in the wire leads is approximately 20 nH (0.02 μH) per inch of lead length.

Now suppose the capacitor of fig. 1B is used in a bypass circuit on a PC board: 1/16-inch PC-board foil has an inductance of 20 nH per inch. If we try to bypass the emitter of a 100-MHz transistor amplifier with a large-value capacitor having ½-inch leads, and the PC-board foil between bypass capacitor and emitter lead is ½ inch, a total of 1½ inches of lead length will exist between the transistor emitter and ground. At 20 nH per inch, this results in 30 nH between emitter and ground. At 100 MHz, the inductive reactance of this combination is of the order of 20 ohms.

The inductive reactance that predominates in a capacitor above its self-
reactance considerations

The idea is to choose a capacitor that is series resonant at the desired bypass frequency. For instance, in the above example, a 68-pF capacitor with \( \frac{3}{8} \)-inch leads and \( \frac{1}{2} \) inch of PC-board foil will series resonate at 100 MHz. The circuit will have minimum impedance at this frequency, and maximum current will flow. Thus the circuit will provide an effective by-pass for unwanted rf energy to ground. (See fig. 2.)

In summary, at frequencies above a capacitor’s self-resonant frequency inductive reactance predominates, and the capacitor doesn’t function efficiently as a bypass element. Below its self-resonant frequency, capacitive reactance predominates and the capacitor looks capacitive to the circuit. This relationship is shown in fig. 3.

graphical aid

Fig. 4 shows experimental results measured with small disc capacitors and a grid-dip oscillator to find resonant frequencies of various capacitor values.

To use the graph in designing a bypass circuit, first ensure that the lead length between the point to be bypassed and ground is as short as possible. Then choose a capacitor value that self-resonates at the frequency to be bypassed.

In short (no pun intended), choose your bypass capacitor with care or you might as well not have a bypass at all.

\[ X_L \ll X_C \quad \text{below } f_{\text{res}} \]
\[ X_L \gg X_C \quad \text{at } f_{\text{res}} \]
\[ X_L \ll X_C \quad \text{above } f_{\text{res}} \]

One-Stop "Shopping" for Everything You Want in a TRI-BANDER QUAD

Why shop around for, and put together, bits and pieces of a tri-band, two-element quad at greater cost particularly when—after all is said and done—Hy-Gain's complete Hy-Quad delivers superior performance?

Yes, Hy-Quad is the only quad that is complete; and here are some of its features:

- Aluminum construction that is made to stay up.
- Spreaders broken up at strategic electrical points with cycolac insulators.
- Individually resonated elements with no inter-action.
- Only one feed line required for all three bands.
- Individually tuned gamma matches on each band with Hy-Gain exclusive vertex feed.
- Full wave element loops require no tuning stubs, traps, loading coils or baluns.
- Heavy duty mechanical construction of swaged aluminum tubing and die-formed spreader to boom clamps.
- Extra-heavy duty universal boom-to-mast clamp that tilts and mounts on any mast 1½" to 2½" in diameter.

If you really want a big signal, buy one at the best distributor under the sun. He's the one that stocks Hy-Gain.

SPECIFICATIONS

Overall length of spreaders ........................................ 305"

amateur applications for WWV-WWVH

WWV (Fort Collins, Colorado), and WWVH (Kauai, Hawaii) transmit frequency and time signals plus other data that provide a variety of helpful services in the modern ham shack, from setting the station clock to measuring modulation. Many frequencies provide calibration points for receivers, frequency meters and calibrators. Standard audio tones permit calibration of audio sources used for testing SSB and FM transmitters. One-second time-marking signals are transmitted continuously by both stations.

WWV broadcasts on carrier frequencies of 2.5, 5, 10, 15, and 25 MHz. WWVH transmits on the same carrier frequencies with the exception of 25 MHz. These standard signals, available day and night, are heard in most parts of the earth. The stability is exceptional, and frequencies are held stable to better than two parts in 10^11. In fact, deviations at WWV are normally less than one part in 10^12 from day to day. Propagation variables such as Doppler effect, when they occur, usually result in a greater fluctuation in the carrier frequencies. This is a result of the path and not the standard.

signal makeup

In addition to serving as a carrier frequency standard, the modulation data carried by the WWV-WWVH transmissions is substantial. The broadcast format is shown in fig. 1. Transmissions from both stations are identical except for a few minor variations that will be mentioned.

The sequence and content for most minutes of each hour are depicted in fig. 2. At 00-second of each minute there is a 0.8-second long 1000-hertz tone on WWV and 1200-hertz tone on WWVH. Just prior there is a voice announcement of Greenwich mean time (GMT). Following the time pulse there are continuous second ticks that continue until the voice announcement that comes before the next time tone. The tone frequency is either 500 or 600 hertz, alternating between these frequencies each minute. The 29th second tick (pulse) is omitted.

The time announcement period extends between 45 and 60 seconds. At WWV the first half of this period is silent except for second ticks. The gmt time announcement is made in a male voice during the second half of this period. The positions switch for WWVH; the announcement comes first in a female voice and the silent period comes second. In those areas where both signals are re-
fig. 1. WWV and WWVH broadcast format.
received you hear the WWVH announcement first followed by the WWV announcement. The first minute of each hour begins with a 0.8-second, 1500-hertz tone on both stations.

Tone signals as displayed on an oscilloscope screen for 500 and 600 hertz frequencies are shown in fig. 3. This signal was demodulated in Pennsylvania from the 15-MHz carrier. Just above the 20-meter band this carrier is a good indicator of the transcontinental path quality on 20 and often for 15. When the WWV signal is very audible in the background it indicates a path is open to the Pacific.

The stations identify on the hour and half hour. One station makes its announcement during the minute before the hour or half hour while the other station identifies itself during the minute after the hour or half hour.

Certain minutes of each hour are set aside for other emission sequences. As shown in fig. 1, no audio tone is transmitted between the 45th and 50th minute of each hour for WWV, and between the 15th and 20th minute for WWVH.

WWV gives propagation forecasts during the 14th minute of each hour, storm warnings during 49th minute.

A 440-hertz tone is transmitted for minute. At WWVH the geophysical alerts are given during the 45th minute and storm warnings during 49th minute.

At 440-hertz tone is transmitted for approximately 45 seconds beginning one minute after the hour at WWVH and two minutes after the hour at WWV. This is a standard musical tone of note A above middle C. In addition, the tone can be used as hourly markers for various types of chart recorders and automated devices.

Special National Bureau of Standards transmissions are allocated a spot three minutes after the hour on WWVH and four minutes after the hour on WWV.

The makeup of the seconds-tick signal is shown in fig. 4. It occupies a time slot of 0.005 seconds and occurs once each second (one hertz repetition rate). The WWV pulse consists of five sine waves of 1000 hertz; the WWVH pulse, 6 cycles of 1200 hertz.

WWV and WWVH transmit a complex time code signal continuously. This code is produced at a one pulse per second rate and is carried on a 100 hertz subcarrier. It provides a standardized timing base containing time-of-year information based on universal time in seconds, minutes, hours and day of the year. It provides a standardized time for use when scientific
observations are made simultaneously at separate locations. Perhaps it may be a help for radio amateur satellite communications systems. Ten-millisecond resolution is obtainable from these transmissions.

**audio calibration**

The standard audio tones from WWV are excellent for calibrating sine- and square-wave audio oscillators. Fixed-frequency and switchable solid-state audio generators such as two-tone oscillators and audio generators for checking fm deviation can be constructed and set on precise frequencies using the WWV signal and oscillographic Lissajous patterns.

Tunable audio or square wave generators also can be set or checked on a number of frequencies using fundamental, harmonic or sub-harmonic patterns. The demodulated WWV signal is applied to the vertical input of the oscilloscope as shown in fig. 5. From table 1 note the variety of frequencies that can be measured using the harmonics and subharmonics of the two standard tones. When necessary other components can be derived from the 440 hertz tone, although it is only transmitted for one 45-second interval each hour.

It would be no problem to construct a switchable tone generator with certain key frequencies that could check the audio filters of CW, sideband, fm and a-m equipment. Several subharmonic and harmonic characteristic patterns are given in fig. 6. These were photographed at night while receiving the 10 MHz WWV signal.

**stable audio oscillators**

P. C. Lipoma uses a Motorola MC1454 integrated circuit in a Wein-bridge oscillator circuit, fig. 7. Frequency of operation is determined by the R1C1 and R2C2 time constants. Usually C1 and C2 are of equal value while the ratio of R1 and R2 is 2/1 to compensate for input and shunting impedances. Typically the capacitor value for 1000-hertz operation is 0.033 μF. To halve the frequency you would double the capacitor value; to double the frequency, halve the capacitor value. Resistor R2 could be made variable to permit precise frequency setting using the WWV standard tones. For example, a two-to-one Lissajous would set the oscillator precisely on 1000 hertz using the 500 hertz incoming standard.

Two such oscillators would give you an excellent two-tone source. An oscillator with switchable capacitors would be good for checking audio filters.

**radio-frequency calibration**

Radio-frequency calibration can also be made by applying the signal source along with the WWV signal to the receiver.

---

**Fig. 5. Setup for Lissajous calibration.**
fig. 6. Typical Lissajous patterns taken while receiving WWV. The test setup used is shown in figure 5.

input, fig. 8. You can calibrate by ear or make a more precise check by using an oscilloscope connected to the receiver i-f system. The pattern swells on each side of zero-beat of the rf oscillator under calibration, fig. 9. You obtain a similar pattern when checking a 5-MHz or 7.5 MHz source as you bring its harmonic output to beat with the 15-MHz WWV signal. In fact, it is easy to calibrate a 100-kHz harmonic oscillator such as those used in the usual crystal calibrator with the same procedure. A good calibration time exists during the 45-50 minute no-tone time interval of WWV-WWVH transmissions.

propagation forecasts

WWV transmits propagation forecasts during the 14th minute of each hour. The telecommunications center of the Depart-
ment of Commerce issues these forecasts daily at 0100, 0700, 1300 and 1900 GMT. Presently each forecast is broadcast unchanged on WWV until the next regular forecast is issued. They give an estimate of the radio quality expected on high-frequency radiocommunications circuits across the North Atlantic path. They apply to typical propagation paths such as Washington-Paris, New York-London and Washington-Reykjavik. However, they are a good guide to propagation conditions for amateur band paths between eastern U.S.A. and Europe.

The forecast statement consists of a letter and a number. The letter is a state of current radio quality over the North Atlantic path at the time of issue. It is expressed in one of three grades:

- **N** Normal or quiet
- **U** Unsettled
- **W** Disturbed

The number in the forecast states the expected value of radio propagation quality on a scale of 1 to 9:

- 1. Useless
- 2. Very poor
- 3. Poor
- 4. Poor to Fair
- 5. Fair
- 6. Fair to good
- 7. Good
- 8. Very good
- 9. Excellent

**geophysical alerts**

Solar and geophysical information is broadcast on WWV 18 minutes after the hour and on WWVH at 40 minutes after the hour. Information is changed daily after 0400 GMT. However, outstanding events are added to the next hourly announcement as soon as they are identified. The information transmitted concerns solar activity, flux and flaring, proton events and flares and conditions of the geomagnetic field. For example the solar flux is announced and a forecast made whether solar activity is to be very low, low, moderate, high or very high. A geomagnetic field broadcast will state whether the field is to be quiet, unsettled or active and when a geomagnetic storm is to be expected.

Radio propagation conditions are affected by many factors including solar and geophysical events, and the weather. Hams who delve into the complex subject of propagation forecasting can tie their results in with the various types of data transmitted by WWV-WWVH. Those of us who keep schedules across the North Atlantic path look forward to those great N9 conditions.

**oscilloscopic sideband patterns**

Service-type oscilloscopes are available at reasonable cost. Most hams own or have access to such an oscilloscope. Most
of these instruments have a frequency response in the vertical amplifier system that extends to 4 MHz and higher.

One of the problems of observing and measuring solid-state units is their relatively low voltage and low power level. The high sensitivity of an oscilloscope with a usable vertical amplifier tends to overcome this observation problem. Observations at 160 meters and even 40 and 80 meters are possible.

In the early days of sideband operation much equipment was home-built and many hams were well versed in ssb adjustment, measurement and observation techniques. Solid-state science and QRP activities have brought about a renewed interest.

The set of oscilloscopic displays shown in fig. 10 were photographed from the screen of a service-type oscilloscope. Each of the patterns is labeled and is appropriate for various types of solid-state sideband gear, including a 160-meter phasing-type IC sideband generator to be covered in a future column.

---

references
audio filter mod

The circuit in fig. 1. is a simple modification of W4NVK's audio filter* that provides variable selectivity with little loss in gain. The 5- to 25-ohm carbon resistor in series with the 88-mH inductor lowers the effective Q of the circuit and broadens frequency response. By adding a rotary switch and several different resistance values you can provide several steps of selectivity. For my purposes one resistor was selected for intermediate bandwidth; a shorting switch removes the resistor from the circuit for sharp selectivity.

Fred Redburn, K6HIU

plug-in toroids

When developing a circuit, you often wish to get it working as soon as possible on one band, with the provision of experimenting on other bands when time permits. A permanent installation is usually out of the question. One simple way to circumvent this problem is to apply a variation of the old plug-in coil technique—use a screw-in toroid.

Two basic parts are the screw-in terminal strip with as many terminals as the tank circuit requires, and a circuit board large enough to accommodate the toroid and its associated capacitors. The leading edge of the board is drilled and filed to accept the terminal strip; the toroid and capacitances are mounted; copper strips are etched to make the connections at the terminal-strip mounting screws. I have used this idea in my direct-conversion receiver and I can easily extend the receiver's coverage with a new screw-in toroid.

It is difficult to approximate the mechanical stability of this setup in touchy oscillator circuits—the thing is as solid as the chassis. With sturdy construction this technique offers better matching in multiband rf finals and drivers. Optimum matching and loading is impossible on different bands by the usual method of tapping down on coils or shorting out sections. The leads associated with the rf tanks in transistor stages must be kept short and as low-loss as possible. You can plug in the optimally tuned circuit for each band without the losses and leads associated with band-

switches and multiband design compromises. On some popular matching systems such as the double-pi section it is easy to lose efficiency by using conventional turns-shorting techniques. With plug-in toroids you get maximum efficiency on each band — this particularly important to the QRP enthusiast.

Adrian Weiss, K8EEG

Franklin oscillator

Although known for many years, the Franklin oscillator circuit is seldom found in amateur-built gear. Yet it offers one of the most stable and at the same time most fool-proof circuits available. Nothing about it is critical. It is almost impossible to foul it up to the extent that it won’t work! There is no tap on an inductor to juggle for proper feedback. There is no capacitance-dividing network to complicate computation of L/C ratios.

Usually, when you see the Franklin oscillator circuit, it is used with high-impedance active devices, vacuum tubes or field-effect transistors. It will work, though, with bipolar transistors by revising the size of the two capacitors that serve as both feedback devices and isolators. (When used with vacuum tubes or fets, these capacitors are very small, about 2 pF, and therefore serve to isolate the tuned circuit from the possible variations of internal capacitance in the tubes or fets.) With low-impedance active devices, such as bipolar transistors, these capacitors must be increased to around 60 pF to maintain proper feedback. This larger capacitance does not seem to have any deteriorating affect upon frequency stability.

The Franklin circuit, as you’ll recognize from the diagram, is closely related to the multivibrator. In fact, that’s what it is, with the addition of a tuned circuit to encourage oscillation on a single frequency and with reasonably good waveform. It will oscillate quite readily if you use hot rf transistors; don’t try to use transistors not designated for rf. If you feed the circuit with regulated dc frequency stability is quite remarkable.

The fourth harmonic of an eighty-meter oscillator, beat against the carrier of a Voice of America propaganda broadcasting station a little above 15 MHz, retained the same audio beat note for hours at a time!

There’s little to be said about construction technique, other than the components involved in the Franklin circuit lend themselves to an orderly array on a perforated board; the physical layout is almost exactly like the schematic diagram. Other than one lead, which runs the full length from back to front, there are no cross-overs. A printed circuit

January 1972
devotee should be able to defeat that cross-over by a long end run!

As with any high-stability low-power oscillator it is best to extract the excitation voltage through an emitter-follower or source-follower stage to avoid disturbing external influences. The buffer stage can be attached to the collector of either transistor. Use as small a coupling capacitor as possible to reduce loading effects.

Carl Drumeller, W5JJ

paralleling power transistors

Theoretically speaking, whenever the power requirements of a particular design cannot be satisfied by a single transistor, several transistors can simply be paralleled to meet the power specifications. In practice, however, this is not always true. Fig. 3 will help explain this.

Assume that two transistors, Q1 and Q2, are parallel connected to carry the current through load resistor R. If both devices receive the same base drive $I_b$, the collector current through each transistor will be determined by its own current gain ($\beta$). For many transistor types, the current gain of a given device can differ by as much as a factor of 10 from another device of the same type and still meet the manufacturer's specifications. If, for example, Q1 has a current gain five times as large as the B of Q2, then Q1 will conduct five times as much collector current as Q2 if both receive the same base current. Obviously, a condition of this sort could lead to the eventual destruction of both devices.

In addition to variations in current gains, variations in base-emitter voltages also affect the current conducted by selected devices. As shown by fig. 4, $V_{be}$ partially determines the base current received by a transistor, and this current produces the collector current. Differences in base emitter voltages ($V_{be}$) between paralleled devices, therefore, will affect the load currents carried by the individual devices.

Identical transistors can be paralleled without an unequal sharing of load currents. Identical devices can be purchased, but they are usually quite expensive in relation to the common garden variety devices. Transistors found on the same integrated circuit chip, incidently, are many times almost perfectly matched and can be easily paralleled.

The adverse effects induced by differences in both current gains and base-emitter voltages in paralleled transistors can be minimized by addition of negative feedback to each individual circuit. This is most easily accomplished by simply placing a resistor in each emitter circuit — the larger the resistor, the smaller the current imbalances in the devices. A point will be reached quickly where further increases in the size of the emitter resistors will not appreciably decrease the current imbalance in randomly selected devices.

Fig. 5 is included as an aid in selecting...
the proper value of resistance. According to Smith, this curve is based on statistical data obtained from randomly selected silicon npn transistors. Bear in mind that the curve is approximate and should be used only as a guideline.

As an example, consider that two parallel transistors are to share a 20 ampere load current equally (10 amperes apiece) and that each has an emitter resistance of 0.25 ohms. From fig. 5 (curve A), it can be seen that a current imbalance of 10% is possible. Since 10% of 10 amperes is 1 ampere, one of the transistors could conceivably conduct 11 (10 + 1) amps. Without the resistors, an imbalance of 35% is possible, and one of the devices could see 13.5 (10 + 3.5) amperes.

If more than two transistors must be placed in parallel, curve B should be employed.

James E. McAlister, WA5EKA

reference
army loop antenna

Dear HR:

The Army loop antenna mentioned in the September, 1971 issue (page 59) and the method of tuning it seems rather lossy and not very rugged mechanically. This is especially true since a good solid capacitor is already built into the antenna.

When coaxial cable is used for loop antenna construction the capacitance between the inner and outer conductors can be used to advantage both mechanically and electrically. A balanced loop such as the one described could be constructed leaving the inner conductor floating and sealed at the feedpoint. Prune-tune as required from the center equally in both directions. Since an unbalanced coaxial feed does not do too much for a balanced antenna it might be just as well to use one side of the coax loop for one feedpoint and the other side for the other, and do all of the prune-tuning at the base where it is handy.

There is one limitation to this type of loop construction: the inductance and capacitance of the coaxial cable used, i.e. the diameter of the loop and the type of the cable. For a quick check I took a 38-foot section of ½-inch semiflexible line (25 pF per foot) which ran in a single-turn loop and grid-dipped it at about 10.5 MHz. A 7-MHz loop antenna with the inner and outer conductors of the same length are a practical size and could be used on 75 meters with a plug-in series capacitor.

Since short loops have quite low radiation resistance, the resistance of all conductors and connections must be kept to a minimum. Coaxial-cable construction should minimize (or eliminate) the need for additional tuning units that are lossy, bulky and do not stand the weather very well. Vinyl-covered coaxial cable is well protected from corrosion and the weather, and the ends can be sealed and painted with corona reducing material; rf power-handling depends upon the size of the cable. There are a number of easy-to-form semiflexible cables from which to choose.

This type of coaxial cable also makes a good solid weatherproof gamma rod capacitor for feeding parasitic beams because it eliminates the corroding slide rod and variable capacitor. Prune-tuning the coaxial-cable gamma matching system may take a little longer but is well worth the effort when it comes to durability. I used such a gamma match on a recently built full-size loop antenna (one wavelength long) to good advantage; the winter snow and icing are rough down here!

Wayne W. Cooper, K4ZZV
Miami Shores, Florida
1296 preamplifier

Dear HR:
In WA2VTR’s “Low-Noise 1296-MHz Preamplifier” article in the June, 1971 issue of *ham radio* the author referred to Hewlett-Packard 5082-2800 hot-carrier diodes as mixers at these frequencies. This device is a good high-level mixer, but the HP 5082-2835 is a much better low-noise uhf mixer.* They are low cost, too.

infrared communications

Dear HR:
In “Gallium Arsenide LED Experiments” in the June, 1970 issue W4KAE describes some equipment for using infrared light-emitting diodes and photodetectors for communications. I’ve experimented since about 1969 with LEDs but the big problem has been building lens systems which are rigid enough to stand up under continuous use, yet allow easy adjustment. This is the hardest part if you don’t have a fully equipped machine shop. I recently came across a piece of equipment which, though designed for something completely different, can easily be converted for communications. A photoelectric cell system designed for burglar alarms, and made by the Alarm Device Manufacturing Company, 165 Eileen Way, Syosset, Long Island, New York 11791.

One version of this series of burglar alarm equipment is the model 1312 Small Laser Photoelectric System which actually uses a LED pulsed at several kHz, and a silicon photodiode detector. It comes in two units, one with the LED and the other with the detector. In

*In addition, the HP 5082-2835 has a typical capacitance of 0.75 pF as compared to 2.0 pF for the 5082-2800. Therefore, it is less apt to operate as a varactor.**
The world's first fully automatic Phase-Locked Loop RTTY terminal unit. 
Now includes DIGITAL SIGNAL PROCESSOR (signal regenerator and parity check)
- Copies shifts from 100 to 1000 Hz automatically
- Auto-track for drifting signals
- Enters “mark-hold” when signal fades
- Input tone range switchable to operate with SSB transceiver audio
- Autostart and selective call available

NEW OPTIONS:
Electronic Speed Converter - lets any 100 wpm machine print 60, 75 or other lower speed signals
Electronic Selective Call - solid state “stunt box”
ASCII and crypto options also available

Write today for detailed specifications
Also see us for tone burst encoders for reliable repeater access.

RTTY afc

Dear HR:

While reading the article, “Automatic Frequency Control for RTTY” in the September, 1971 issue, I came across one point that should be clarified for the benefit of your readers. In the article W5NPD states that in most RTTY signals 2975 Hz is used as the mark tone and that this tone is present for a larger percentage of the time. It should be noted that the standard mark tone has been 2125 Hz for years; most, if not all, AFSK systems use 2125 Hz for mark. Many builders have omitted a normal/reverse switch and straight wired the unit in the normal 2125-Hz position.

To use 2975 Hz as the mark tone the operator should listen in the upper sideband (bfo low) position with the normal/reverse switch on the converter in the reverse position. For those who use their converter in the normal (bfo high, lower sideband) position, it is feasible to build the afc using 2125 Hz as the standard for the discriminator tuned circuits.

burglar alarms it has a guaranteed range of 800 feet (assuming no fog or rain), but most units can be used for quite a bit more. Both units are complete with mounting hardware, optics, an easily adjustable swivel arrangement and case, and are designed for installation by inexperienced installers. To convert it to communications it is only necessary to modulate the pulsing circuit to produce pulse frequency modulation and detect the fm in the output.

For serious experimenters the price of $125 may make the system of some interest, but it is hard to get, since the manufacturer sells only to burglar alarm installation companies. If your local alarm installer refuses to sell you one, or if he wants too much of a markup, I can get a limited number at the above price, including shipping.

ham wattmeter

Designed especially for the amateur radio market, three new rf wattmeters are now available from Bird Electronic Corporation. Two models will cover the frequency range from 1.8 through 30 MHz and the third covers from 50 to 150 MHz. The Model 4350 measures forward and reflected power in two ranges: 200 w and 2000 w, while the Model 4351 has ranges of 200 w and 1000 w. The Model 4352 has ranges of 40 w and 400 w covering the two vhf bands of six meters and two meters.

The new line of wattmeters are designated Ham-Mate,* and use the well known Thruline construction, made famous in the industrial field by the Bird Model 43. The new wattmeters emphasize dependable rf power measurement. Special attention is given to the directivity of the Ham-Mate, which is the ability to differentiate between rf power flowing in opposite directions in a transmission line. The new Ham-Mate has a minimum of 20-dB directivity which assures meaningful reflected power and vswr measurement. All three models sell for $79. More information is available by using check-off on page 94, or by writing to Bird Electronic Corporation, 30303 Aurora Road, Cleveland, Ohio 44139.

scanning receiver

A new fm monitor receiver which covers both low- and high-band vhf channels has been introduced by the E. F. Johnson Company. Called the Duo-Scan* monitor receiver, it features dual-conversion circuitry and a double ceramic filter. The two ceramic filters result in sharp selectivity characteristics and an adjacent channel rejection of 60 dB. Another feature of the new Duo-Scan is an integrated-circuit limiting system. This IC limiting produces a symmetrically hard

*Ham-Mate and Thruline are registered trademarks of the Bird Electronic Corporation.
pattern that effectively eliminates noise. The receiver’s all solid-state circuitry has a sensitivity of 0.4 $\mu$V for 12 dB SINAD.

The Duo-Scan receiver has eight channels which can be any low- and high-band combination. If just one low-band frequency is to be monitored, for instance, the remaining seven channels can all be used for high-band monitoring. This allows you to monitor all the local 2-meter repeaters and the activity on 52-525 MHz. Programming channels for high- or low-band is done with simple jumper plugs, requiring no rewiring or tuneup adjustments. Each channel has a lock-out pushbutton to permit bypassing of that channel if desired. The monitor can also be used in the manual mode with the pushbuttons used to lock in channels.

A built-in power supply allows both 12-Vdc mobile operation and 117-Vac base-station operation. Other features include noise-operated squelch, channel selector indicator lights and external speaker jack. Suggested price for the receiver is $169.95. Complete details are available from local E. F. Johnson dealers, by writing directly to the E. F. Johnson Company, Waseca, Minnesota 56093, or by using check-off on page 94.

crystal discriminators

Spectrum International has added five new crystal discriminators to their line of crystal products manufactured by KVG in West Germany. The new models, XD 9-01, XD 9-02 and XD 9-03 are designed for RTTY, AFC and lab measurements with a 9-MHz center frequency, the model XD 107-01 for narrow-band fm
and the model XD 107-02 for wide-band fm. Both fm versions have a center frequency of 10.7 MHz.

Crystal discriminators make simple and effective demodulators for fm and RTTY receivers. The receiver i-f output is fed into the discriminator input, and audio output results without the tedious alignment and power requirements of ratio detectors and LC discriminators. Input and output transformers are included in the hermetically sealed crystal discriminator package. Compatible with tube or solid-state equipment, these miniaturized discriminators are designed for replacement in high-density conventional equipment along with new miniaturized designs.

The line of five filters include models with deviation between 5 and 50 kHz. All models have standardized input terminations of 500 ohms and outputs of 100 kilohms. Models are priced at $14.95 and $16.95. Complete technical specifications are available from Spectrum International, Box 87, Topsfield, Massachusetts 01983 or use check-off on page 94.

**sniff-it rf detector**

The Dycomm Sniff-It turns any vtvm or vom into a versatile rf detector. The model DS-1 Sniff-It indicates the presence of rf from the lowest intermediate frequencies up to uhf at power levels ranging from one milliwatt to 250 watts. A typical reading with the Sniff-It connected to a Simpson 260 vom on the 50-μA range would be 5 to 10 μA when placed near a 1-mW 450-MHz oscillator.

Uses for the Sniff-It include troubleshooting receivers (by indicating the presence of signals near the rf and i-f stages and output from the local oscillator), aligning converters, peaking crystal oscillators and QRP projects and balancing push-pull amplifier stages (by placing the Sniff-It next to each stage and adjusting until equal readings are obtained). When tvi proofing the station, the Sniff-It detects rf leaks around the transmitter cabinets, feedthrough to cables, coax shield breaks leaking rf, local oscillators pumping out too much rf and unneutralized rf stages.

The Sniff-It can also be used in adjusting antennas. You can run the Sniff-It along a ¼-wave whip and check for nulls. If the null is at the end of the antenna you know you have the right length. If the null comes before the tip of the antenna you know that the antenna is too long. Similarly, antenna feedlines and 5/8-wave-length verticals can be adjusted by checking for nulls and comparing your findings to the theoretical figures found in any good antenna handbook.

By choosing the current range on the vom, the Sniff-It detects a wide range of power levels. A vtvm can be used to show relative voltage drops across a load resistor.

The Sniff-It is available for $5 from Dycomm, 948 Avenue E, Riviera Beach, Florida 33404. More information is available by using check-off on page 94.

**fm transceiver with frequency synthesized receiver**

Clegg’s new FM-27 is a completely solid-state mobile transceiver using a Crystiplexer tuner. The Crystiplexer is a new synthesizing system that allows any channel in the range of 146-147 MHz to

January 1972
be monitored with crystal precision — but without the need for additional crystals. To monitor any specific frequency within this band the operator merely sets the two receiver controls to numbers corresponding to the desired frequency. To monitor 146.94, for example, the operator sets the first control to 9, and the second to 4.

Receiver selectivity is rated at 70-dB adjacent-channel attenuation. Sensitivity is rated at better than 0.35 µV for 20-dB quieting.

The transmitter portion of the new transceiver is 10-channel solid-state unit with 20-25 watts rf output. The entire transceiver weighs less than three pounds and is packaged in a rugged anti-theft case with a special locking-clamp mounting. Two crystal-controlled transmit channels and a push-to-talk microphone are included at the sales price of $449.95.

Further information is available through check-off on page 94 or by writing to Clegg Division, International Signal and Control Corporation, Box 388, R. D. 3, Lititz, Pennsylvania 17543.

tube and transistor substitution guide

Tab books has brought out the updated 3rd edition of their handy servicing substitution guide. The 256-page "1972 Popular Tube/Transistor Substitution Guide" is designed to fit in a tube caddy and lists 99% of the tubes and transistors which normally need replacing in home-entertainment equipment. Moreover, only readily-available and comparably-priced substitutes are listed — no need to search through lists of tubes and transistors rarely used.

This brand-new volume contains 8 sections — four devoted to tubes and four to transistors. Section 1 provides a cross-reference of popular American receiving tubes, listing substitutes which have similar or superior characteristics and which require no mechanical changes or circuit modifications. For convenience, the best substitute is listed separately from others that may be used. Section 2 lists substitutes for popular tube types found in commercial and industrial equipment. Again, the most appropriate substitute is identified. Section 3 provides a cross-reference of popular foreign/American tube types, and Section 4 illustrates base diagrams for all tubes.

Section 5 contains a complete listing of popular American transistors and the most readily-available, popularly-priced substitutes. Section 6 lists American substitutes for the most often encountered foreign transistors. Section 7 lists general-purpose replacements, offered by leading manufacturers. Section 8 illustrates base diagrams key to the original type listings.

The vinyl-covered version of the book costs $4.95 and the paperback is $2.95 from Tab Books, Blue Ridge Summit, Pennsylvania 17214. More information is available by using check-off on page 94.

audio ics

Radio amateurs and experimenters may benefit from two new audio integrated circuits introduced by Motorola. The two new ICs, while designed for such consumer product applications as televisions, radios and portable phonographs, should also work well in many amateur receiver and experimental designs.

The MFC9020 is rated at two watts output and is housed in a plastic package with two heat dissipating tabs. The MFC6070 is the one-watt version and is supplied in a smaller case. Printed-circuit board layouts which can be used interchangeably with either device, are shown on the respective data sheets. The boards are designed for speaker return to either ground or to the positive supply. Input impedance is in the order of a megohm, and only 200 mV input is required for full output. Total harmonic distortion averages about 1% at rated output.

For further information, please contact the Technical Information Center, Motorola Inc., Semiconductor Products Division, Box 20924, Phoenix, Arizona 85036 or use check-off on page 94.
MINI-MITTER II
Portable Transceiver Kit
Handheld! QRP!

ALL TRANSISTOR SSB TRANSCEIVER KIT DESIGNED EXPRESSLY FOR THE HAM

- BIG TRANSCEIVER SOPHISTICATION
- ALL SOLID STATE
- EASY TO ASSEMBLE
- SIMPLE TO OPERATE
- POWERED BY 8 Ni-CAD BATTERIES
- RUGGED ALL METAL CASE
- 3 3/8" X 1 3/4" X 10" H
- WEIGHS LESS THAN 1 LBS
- PRINTED CIRCUIT BOARD
- QUALITY COMPONENTS

SSB GEAR THAT GOES WITH YOU! Introducing the new, delightfully wild MINI-MITTER II KIT designed especially for the Ham. Get it together in a few enjoyable hours of creative fun. Carefully engineered using the latest techniques this fully transistorized solid state transceiver features commercial grade components, unique switching, a Collins Mechanical Filter along with the easy to follow instructions for assembly. The transceiver is powered by 8 Ni-Cad Batteries easily accessible through a hinged door at the rear of the case for recharging. The printed circuit board chassis and the complement of Field Effect Transistors along with Integrated Circuits ensures the highest performance, yet simplifies the circuitry for easy assembly. The tune-up procedure requires no special test equipment since all of the tuned circuits are pre-tuned at the factory and need only minor adjustment. For final setting and performance checks a receiver is recommended.

MODEL CSP-11
PRICE $120

Simply connect the Comdel CSP-11 between your audio source and equipment and get instant voice clarity with a 10 dB increase in talk power. Unlike conventional speech clippers the CSP-11 tailors the audio bandwidth and introduces no harmonic distortion. It is equally effective in Audio AM, FM and SSB systems. For further information call or write.

reference data for radio engineers

Whether you are in amateur radio, commercial radio or electronics, the new fifth edition of "Reference Data for Radio Engineers" is an invaluable tool. This new compilation of approximately 1150 pages and 1350 illustrations plus a comprehensive index and cross-index was made by an extremely qualified group of practicing engineers, professors, and industry and government experts under the direction of the staff of the International Telephone and Telegraph Corporation.

The book is skillfully written, greatly enlarged and meticulously revised and edited. Approximately 50% of the text is new material, including seven subject areas not covered by the fourth edition. In addition to the basic phases of electronics, there is new material on micro-miniature electronics, space communications, navigation aids, quantum electronics and many other topics.

In 1942, the British subsidiary of ITT, Standard Telephones and Cables Limited, saw the need for a complete, reliable reference source for the radio and electronics engineer. Thus, the first edition of this reference was developed as a 60 page brochure. Because of the enthusiastic reception of information compiled under one cover, the brochure has grown into a book-length volume.

Its usefulness, however, is not restricted to the practicing radio and electronics engineer for whom it was originally prepared. Reference Data for Radio Engineers has been accepted for classroom use in over 200 leading colleges and universities in the United States.

The text is generously supplemented with literally hundreds of charts, nomographs, diagrams, tables, circuit information, illustrations and an inexhaustible index and cross-index. 1150 pages, hard bound. Published by Howard W. Sams & Company. $20.00 postpaid from Comtec Books, Post Office Box 592, Amherst, New Hampshire 03031.
As a further service to our amateur friends, Swan now offers a Revolving Credit Plan that permits you to purchase any Swan equipment, and charge it!

If you wish, you can pay your charge each month within 25 days of your billing date with no finance charge. Or if you prefer, you can spread your payments over a number of months, and your monthly payments will be adjusted accordingly depending on your balance.

Now it's easier than ever to purchase Swan equipment. Just order your equipment from the factory, our East Coast branch, or one of our participating dealers, and say, "Charge it!" Once your account has been opened, you can add to your account at any time.

An important fact to remember is that this financing is available directly from Swan. We handle your account from start to finish. Unlike many credit plans offered today, Swan WILL NOT sell your account to some finance company.

Mail the adjacent coupon in today, and we will send you complete information and your Swan Credit Application by return mail, and your account can be opened in just a few days.

**Swan Revolving Credit Service**

RUGGED, HEAVY-DUTY BUNK-TO-TALK

NEW, 6-L/H, 4-1/2 R, 45/8".

R-20 RECEIVER
Made by Aircraft Radio Corp., works on 28 V, includes 4 tubes: 2/12A6W, 12A7X, 12A7T. Size: 6-1/2"x4-1/2"x5/8".
LIKE NEW, with tubes and crystals...
$9.95

HANDMIKE
Rugged, heavy-duty carbon hand mike with press-to-talk switch. Equipped with 4-ft cord & phone plug.
SPECIAL
NEW, boxed...
Each $1.88 2 for $3.25

2" DC VOLT METER
Mounts in 2-1/8" hole, Flange diameter 2-5/8".
Two scales: 0-15 and 0-600, Calibrated for use on steel panel, Standard brand.
SPECIAL
NEW, boxed...
Each $1.75 2 for $3.00

TG-58 TELEGRAPH SET
for code communication or code practice. Portable, with hinged lid. Two or more units operate up to 25 miles apart. Bell coil system, 100 cycle bowler, key, headpiece, canvas case, book.
Size 5-1/2x5-1/2x10"...
LIKE NEW...
$8.95

BC-733 RECEIVER
Receives radio signals being transmitted by US satellites on approx. 108 Mc. AM, crystal-controlled on 6 preset freqs. In 108.3 to 110.3 Mc range. Operates on 12/24 V DC & 220 VDC 60 Mc, Complete with 10 tubes. Can be converted to FM Receiver 80 to 108 Mc, Exc., Used...
$5.95

BC-732A Control Box for above...
1-75

T-41 / APS-18 TRANSMITTER
ANTENNA: Unf. Designed for 115 V 800 to 1400 cps. Tubes included are two 15E and one 15B. Complete with shock mounts and blower motor, 7"x8"x18", NEW...
$8.95

 BC-223AX TRANSMITTER
25 Watt, CW, MCW, Voice, Crystal control on 5 pre-selected channels, range 2000 to 5000 Kc by use of 3 plug-in units, Complete...
BRAND NEW...
$27.50

APN-1 FM TRANSMITTER
400-450 Mc, Freq., modulated by moving coil transducer. Easily converted for radio control or 70 Mc. Complete with 14 tubes, dyn...
BRAND NEW...
$9.95

IP-69/A/ALA-2 INDICATOR
3" scope.
Front panel: Vertical Pos., Horizontal pos., Intensity, focus, gain, width, center freq., Pan.
Operates on 115 V 300 to 1000 cps.
Complete with tubes, LIKE NEW...
$27.50

TELEPHONE TYPE RELAY
Made by J.H. Bunnell, has adjustable sensitivity. 150 ohm coil...
BRAND NEW...
$3.45

UNIT 645 TRANSCIEVER
15 tubes, 435 to 500 Mc.
Easily adapted for 2-way voice or code on Ham, Mobile, Television Experimental, and Citizens Bands. With tubes, less power supply in factory carton, BRAND NEW...
$16.95

TRANSMITTER has 4 tubes: WE-314A, 2-566, 707
RECEIVER has 11 tubes: 2-955, 4-417, 2-765, 3-217
RECEIVER & 40 Megacycles
Size: 10-1/2"x13-1/2"x4-1/2"...
Ship wt 25 lbs.

SPECIAL PACKAGE OFFER: BC-645 Transceiver, Dynamotor and all accessories, including mounting, UHF Antenna Assemblies, control box, complete set of connectors and plugs.
BRAND NEW...
$26.95

TG-34A CODE KEYER, self-contained, automatic, reproduces code practice signals from paper tape.
5 to 12 WPM key practice. Brand new, complete manual, test key, take-up reel and AC line cord...
$24.50

Code practice tapes for above...

INTRODUCING THE FINEST TRAP VERTICAL ANTENA AT ANY PRICE

GOLDEN SWAN

PROVIDES MAXIMUM PERFORMANCE ON 10, 15, 20 AND 40 METERS.

LARGE HIGH Q TRAPS
Precision wound on pre-grooved Lexan coil form, assuring coils will hold their tuning indefinitely and provide many times the “Q” of the closest competitor. These patented high Q traps permit your transmitter power to be radiated out as signal rather than be dissipated by heating up the coil.

LOW SWR
A close inspection of the SWR curves of the Golden Swan shows that it has extremely low SWR and broad band characteristics.

Use Swan’s new Revolving Credit Service.

Gentlemen:
Please send me your Golden Swan vertical trap antenna.

Many thousands of you have be-
come very familiar with the vari-
ous Radio Society of Great Britain
books and handbooks, but very
few of you are familiar with their
excellent magazine, Radio Com-
munication.

It includes numerous technical
and construction articles in addi-
tion to a complete rundown on
the month's events in amateur
radio. Surely a most interesting
addition to your amateur radio
activities.

We can now offer this fine maga-
azine to you along with the other
advantages of membership in the
RSGB (such as use of their out-
going QSL Bureau) for $9.60 a
year.

comtec
Box 592 • Amherst, New Hampshire 03031

A New Magazine?

Not really. New in the U.S.A. perhaps,
but very well known in Great Britain and
now being offered to you here.

RADIO CONSTRUCTOR is almost exclu-
sively construction material. Clearly writ-
ten, concise articles give you full details
on:
- Audio Construction Projects
- Receiver Construction Projects
- Transmitter Construction Projects
- Test Equipment Projects
- Radio Control Projects
... and much more

Try a subscription to this interesting
magazine, we are sure that you will not
be disappointed.

ONE YEAR SUBSCRIPTION — $6.50

WHAT'S NEW FOR '72?
IMPROVED PERFORMANCE • MORE POWER • BETTER RELIABILITY

DYCOMM OFFERS MORE WATTS PER

DYCOMM, the RF People, high volume production continues to save you money. DYCOMM broadband, no tuning, ready to use boosters can increase your transmitted power up to 45 times. Fully automatic, hands off operation.

DYCOMM makes a booster-amplifier for use with virtually every 2M FM rig.

DYCOMM boosters are reliable, inexpensive, straight forward, small in size and big in performance.

Over 2,000 satisfied users. No one has EVER paid a cent for repair; in fact, part of our warranty reads:

... If you ever have a problem with your booster take it to any DYCOMM dealer and he will replace it free of charge. If it is out of warranty he will give you another booster and we will bill you for repairs if it seems appropriate ...

C "FM Booster", 4-12W in, 15-30 out. 10W input/25W output. $69.95

D "Block Booster", the most widely used amplifier in America. Typically 55-65W output on a HR-2A. 9-12W input/40-55W output. $99.95

E "Brick" or TR-22 Booster, one of the most popular. your 1-2W HT can push out 20-25W. $79.95

ES "Super Brick/TR22 Booster", Now you can have from 35-45W for .8-2 watts input. Typically 30W output/1W input. $99.95

10-0 The ultimate in solid state power. 7.15 watts input will put out 80W min., 125W max. Typically 100W output/10W input; 90W minimum output/10W input. $185.00

35-0 Provides 80-100W output for 25-40W input, typically 100W output for 35W input. $165.00

All boosters have automatic low insertion loss in/out switching. All operate from 12-15V DC. Draws no current in standby.

They are rugged; built to take vibration, load mismatch and over-voltage.

To order: See your nearest DYCOMM dealer, if none near you, order direct and add $1.55 for shipment. Dealer inquiries invited.

Isn't it time you also went DyComm?

Eliminate Annoying "Channel Chatter"

The new Probe-Master SELECTIVE CALLING UNIT (SCU) cancels out all undesired signals while you hear only the calls from selected stations. Each SCU is a precision, system engineered encoder/decoder which is fully compatible with your AM or FM rig. Install it in your rig or custom enclosure with switches to suit your taste. Features include 5 separate calling channels, automatic reset to selective monitoring following each call, solid state design using integrated circuits, stability with temperature and voltage changes, and simple power requirements of 9 to 15 volts AC or DC at 4 ma. (requires only a series resistor for immediate delivery send $37.50 ($42.50 for 6.3 VAC option) to PROBE-MASTER Electronic Services, Inc. Rt. 1, Box 139-D Lewsville, Texas 75067

More Details? CHECK-OFF Page 94
POTOMAC AREA VHF SOCIETY challenges any other club to attain a better average score during the January 1972 VHF Sweepstakes. To accept this challenge, any club secretary or individual member must submit (postmarked no later than January 7, 1972) a list of the calls of the members of his club, and (postmarked not later than February 15, 1972) a list of the calls of the stations, operated entirely by club members, which participated. Mail to K3LNZ as per Callbook address. Club average scores will be calculated from the results in QST by the following formula: Club aggregate score divided by number of members multiplied by percentage of members participating. A club must have at least six members, and must have been in existence on January 1, 1971. At least 50% of the members must have been in the club on July 1, 1971. Challenger's decision is final as to any highly-unusual lists of members and/or calls. A multi-top station counts as one member participating. If at least five clubs respond to this challenge, it will be repeated next year. Let's get something going where club size doesn't decide who carries home the bacon!

WANTED: I.F. PLUG-IN unit complete, for Collins R39/VURR. K1GVA, 61 Warwick, Portland, Maine 04102.

Ferris #32 (+) Field Strength Meter is a red-hot receiver from 150 KHz to 20 MHz, only 95.00

Empire Devices NF-114 RFI meter is a red-hot receiver from 150 KHz to 80 MHz.

295.00

Spectrum Analyzer Give-Away: Polaroid TSA with 571 head; 10,000 MHz. Looks good, sold as-is... 350.00

We have the best test-equipment & oscilloscope inventory in the country so ask for your needs . . . don’t ask for an overall catalog . . . we also buy, so tell us what you have.

R. E. GOODHEART CO. INC.
Box 1220-HR, Beverly Hills, Calif. 90213

BROADBAND AMPLIFIERS at a price you can afford

The BBA-1 series offer high gain over the HF to UHF region with Noise Figures as low as 3dB max. BBA-1PB covers 30 to 400 MHz with 17dB, ±1dB, gain and 3.2dB, maximum Noise Figure. The BBA-1PB covers 3 to 500 MHz with gain between 10 and 20dB, and maximum Noise Figure of 3.0 dB. For less critical use order the BBA-1, which has the same coverage as the BBA-1PB but with slightly reduced UHF gain and higher Noise Figure. They are all a bargain! BBA-1PB, BBA-1PB-$45.00, BBA-1-$30.00 FOB Baltimore

RADIATION DEVICES CO.

ANNOUNCING

TWO NEW FREQUENCY STANDARDS

Mark 9, 5 kHz 600-1000 Hz, 25, 50, and 100 kHz, selected by front panel switch. Zero adjust for WWV calibration, handsome cabinet, 100KHz crystal included and a six month warranty. Model 100-5PB portable (battery operated) or Model 100-5PS for fixed station use (power line operated). $28.95 each PPD. Write for brochure.

420 Maplewood Ave., Springfield, Pa. 19064

CRYSTAL FILTERS AND DISCRIMINATORS

by KVG of West Germany

9.0 MHz FILTERS

XF 9A (5)* 2.5 kHz SSB $23.12

XF 9B (8) 2.4 kHz SSB $32.85

XF 9C (8) 3.75 kHz AM $35.40

XF 9D (8) 5.0 kHz AM $35.40

XF 9E (8) 12.0 kHz NBFM $35.40

XF 9M (4) 0.5 kHz CW $24.49

XL10M (10) 0.5 kHz CW $65.64

TECHNICIAN WANTED

A leading VHF Component Manufacturer requires a technician who has a broad interest in improving the state of the art in high frequency component design. Duties will include developing RF testing techniques, test fixtures, and special circuitry as required. Familiar with testing methods and processes. Standard VHF components desirable. Second Call Area. Write to Box AB, Ham Radio, Greenville, N. H. 03048.

METERS GALORE. All new, American made, except as noted.
0-15v AC; 0-50v DC; or 0-500v DC. 4-1/2" sq. Choice of scales 0-50ua & 0-250 ma DC (no shunt); or 0-15 KV DC (no multiplier). Choice, mix or match.

@ $25.00; ea. $6.50
0-100v AC; or 0-500v DC. 3-1/2" sq. Choice, mix or match.
@ $15.00; ea. $4.50

More Details? CHECK—OFF Page 94
1. **MXX-1 TRANSISTOR RF MIXER**
   A single tuned circuit intended for signal conversion in the 3 to 170 MHz range. Harmonics of the OX oscillator are used for injection in the 60 to 170 MHz range. Lo Kit 3 to 20 MHz, Hi Kit 20 to 170 MHz (Specify when ordering) $3.50

2. **SAX-1 TRANSISTOR RF AMP**
   A small signal amplifier to drive MXX-1 mixer. Single tuned input and link output. Lo Kit 3 to 20 MHz, Hi Kit 20 to 170 MHz (Specify when ordering) $3.50

3. **PAX-1 TRANSISTOR RF POWER AMP**
   A single tuned output amplifier designed to follow the OX oscillator. Outputs up to 200 mw, depending on the frequency and voltage. Amplifier can be amplitude modulated. Frequency 3,000 to 30,000 KHz $3.75

4. **BAX-1 BROADBAND AMP**
   General purpose unit which may be used as a tuned or untuned amplifier in RF and audio applications 20 Hz to 150 MHz. Provides 6 to 30 db gain. Ideal for SWL. Experiment or Amateur $3.75

5. **OX OSCILLATOR**
   Crystal controlled transistor type. Lo Kit 3,000 to 19,999 KHz, Hi Kit 20,000 to 60,000 KHz (Specify when ordering) $2.95

6. **TYPE EX CRYSTAL**
   Available from 3,000 to 60,000 KHz. Supplied only in HC 6/U holder. Calibration is ±0.02% when operated in International OX circuit or its equivalent. (Specify frequency) $3.95

---

**for the commercial user**

**INTERNATIONAL PRECISION RADIO CRYSTALS**

International Crystals are available from 70 KHz to 160 MHz in a wide variety of holders. Crystals for use in military equipment can be supplied to meet specifications MIL-C-3098B.

**CRYSTAL TYPES:**
- (GP) for "General Purpose" applications
- (CS) for "Commercial Standard"
- (HA) for "High Accuracy" close temperature tolerance requirements.
The proven 'ONE'
a transceiver by Tempo

More than a year ago the Tempo 'ONE' was introduced to the amateur world as the new 'ONE'. Now with thousands in use it's the proven 'ONE'. Look at its price and then look at its specifications. Add to this its record of reliability and the result can be summed up in one word...value.

Specifications

Frequency Range: All amateur bands 80 through 10 meters, in five 500 kHz ranges: 3.5-4 MHz, 7-7.5 MHz, 14-14.5 MHz, 21-21.5 MHz, 28.5-29 MHz. (Crystals optionally available for ranges 28-28.5, 29-29.5, 29.5-30 MHz.)

Solid State VFO: Very stable Colpitts circuit with transistor buffer provides linear tuning over the range 5-5.5 MHz. A passband filter at output is tuned to pass the 5-5.5 MHz range.

Receiver Offset Tuning (Clarifier): Provides ±5 kHz variation of receiver tuning when switched ON.

Dial Calibration: Vernier scale marked with one kilohertz divisions. Main tuning dial calibrated 0-500 with 50 kHz points.

Frequency Stability: Less than 100 cycles after warm-up, and less than 100 cycles for plus or minus 10% line voltage change.

Modes of Operation: SSB upper and lower sideband, CW and AM.

Input Power: 300 watts PEP, 240 watts CW

Antenna Impedance: 50-75 ohms

Carrier Suppression: -40 dB or better

Sideband Suppression: -50 dB at 1000 CPS

Third Order Intermodulation Products: -30 dB (PEP)

AF Bandwidth: 300-2700 CPS

Receiver Sensitivity: 1/2 µV input S/N 10 dB

AGC: Fast attack slow decay for SSB and CW.

Selectivity: 2.3 kHz (-6 dB), 4 kHz (-60 dB)

Image Rejection: More than 50 dB.

Audio Output: 1 watt at 10% distortion.

Audio Output Impedance: 8 ohms and 600 ohms

Power Supply: Separate AC or DC required. See AC "ONE" and DC "ONE" below.

Tubes and Semiconductors: 16 tubes, 15 diodes, 7 transistors

Tempo 'ONE' Transceiver $298.00*

AC/ONE Power Supply

117/230 volt 50/60 cycle...

$ 99.00*

Butler, Missouri 64730 816/679-3127
Right on! Power tubes have come a long way since the nostalgic days of EIMAC's first triode, the 150T. All the way up to the giant X-2159 developmental tetrode having a plate dissipation of one and one-quarter megawatts.

The amazing X-2159 powerhouse can develop two megawatts of CW power up to 30 MHz or so with up to 17 decibels stage gain. It can also be used as a 60 kilovolt, 1,000 ampere switch tube, or as an extremely high power pulse modulator.

Two EIMAC X-2159s can be used in a 2.5 megawatt, 100% plate modulated medium or shortwave transmitter. At VLF, moreover, two X-2159s can develop 4 megawatts of CW power.

The X-2159 is a thought provoking example of EIMAC's capability to produce tomorrow's tube today.

For full specifications on EIMAC's new super power tetrode and other outstanding products write: EIMAC Division of Varian, 301 Industrial Way, San Carlos, California 94070. Or contact any of the more than 30 Varian/EIMAC Electron Tube and Device Group Sales Offices throughout the world.
